A project report submitted for the award of MEng Electronic Engineering

A STEREOSCOPIC VISION ROBOT

by Henry S. Lovett

I don't like this. Consider changing...

This report describes the research, design, build and test of a stereoscopic robot using two Omnivision OV7670 cameras and an Atmel AT32UC3C0512C Microcontroller. A custom PCB was designed to fit a wheeled base. The report is in two main parts, hardware design and vision algorithms. The hardware design section describes the prototypes and design of the subsystems.

The vision algorithms section discusses range finding from stereo images, comparison algorithms between stereo pairs and the implementation and test of a two dimensional fast Fourier transform on an AVR.

The final product is a small mobile robot equipped with cameras and capability of image processing. The device has the ability to execute a predefined set of commands in an automatic stand alone way. The robot can also be used as a shell terminal to debug and remote control.

C_b	$2\pi r_b$

Acknowledgements

I would like to thank Professor Steve Gunn whose help throughout the year was invaluable and for the weekly meetings no matter where he was in the world. I would also like to thank my friends and family for their support and help throughout my degree and with proof reading, to Tom for our years of being lab partners during our time here, and finally to Alice for asking the two golden questions that solved 90% of my problems whenever I had one; “Is it connected?” and “Is it switched on?”.

All work presented in this report is my own unless otherwise stated or referenced.

Chapter 1

Introduction

The original idea for the project was a stereoscopic mapping robot, similar to [Goebel \(2012\)](#). This would autonomously search an area and return an occupancy map ([Thrun, 2003](#)). However, due to time constraints, the image processing aspects remain prototyped in MATLAB, but not implemented in C. The end robot is able to capture stereo image pairs, move with reasonable accuracy compute Fourier Transforms. The robot can run a predefined set of commands automatically or act as a shell terminal.

Stereoscopy in computer vision is the ability to calculate the locations and depths using images from two or more cameras, which are used to triangulate and estimate distances ([Saxena et al., 2007](#)). By using two cameras on the same plane, separated by a set horizontal distance, the depth of the observed scene can be perceived by the system.

Stereo vision is a small section of computer vision which is widely used in many applications, including Microsoft's Xbox Kinect ([Microsoft, 2012](#)), where stereo vision is used to locate a game player in order to use their movements to control the game. [Mrovlje and Vrančić \(2008\)](#) uses stereo vision to be able to locate the distance to a marker.

Leap Motion?

The stereo vision robot discussed in this report is a low cost alternative to other robots which use laser range finders or high quality cameras ([Se et al., 2002](#)). The robot used the base seen in figure [1.1](#) and use two OmniVision OV7670 cameras delivering QVGA format images.

Figure 1.1: The base of the robot

The final robot designed could be used for a variety of applications. The robot can perceive depth of the captured area so can avoid obstacles and navigate. The robot could also be adapted to stream the camera data to a remote computer and be controlled by a user to explore unknown and potentially hostile areas safely.

1.1 Project Management

In order to reduce the risk within the project, all aspects of potential issues were looked at and are summarised in table 1.1. A Gantt chart of how time should be spent can be seen in figure A.1.

The project was designed in stages - first, gaining operation of all the basic sections; movement, image capturing, image detection algorithms etc. These were then be brought together once tested to create the final product. This meant functionality was obtained of the basic aspects before addressing more complex issues.

Risk	Severity	Prevention
Components not arriving on time	High	Order parts as early as possible
Project not fulfilling specification	High	Develop in stages to obtain functionality in parts. Ensure enough time is allocated to the project.
PCB Design is incorrect	Medium	Check the design carefully and get second opinion.
Failure of personal computer causing data loss	Low	Keep back ups of all work on Devtrack Git repository and Dropbox.

Table 1.1: A list of risks and the prevention steps taken to reduce their impact

Chapter 2

Research

The research for this project was split into three sections:

1. Hardware
2. Software, broken down into:
 - (a) Firmware, and
 - (b) Image Processing

Hardware and firmware research will be discussed in this section. Image processing is looked at in detail in chapter 4.

2.1 Hardware Research

2.1.1 Microcontrollers

The budget for the design was £80 (not including PCB). The choice of microcontroller was an important one, as a compromise between cost, power and usability had to be made. There are two main brands of microcontrollers present in the consumer market: ARM and AVR.

ARM is an architecture which is developed by ARM Holdings. ARM devices come in a many varieties: ARM9, ARM7, Strong ARM, ARM Cortex etc. Whilst ARM Holdings do not fabricate and sell the devices themselves, many companies, such

as Texas Instruments, use the architecture and manufacture their own devices. ARM cores are based on a RISC Harvard architecture and tend to be 32-bit with a high clock speed. ARM microcontrollers have on chip support for SPI, I^2C , PWM, ADCs and can have Flash, SRAM and EEPROM memory built-in. For this comparison, the Stellaris by Texas Instruments will be examined.

Atmel have a variety of products in the microcontroller market, which have an AVR core that is a predominantly 8-bit, Harvard RISC architecture. They range from a low clock speed device for the hobbyist (ATMega and ATTiny series), to an improved 8-bit variant (XMega), and a 32-bit architecture (AT32UC3). XMegas and AT32s tend to have higher clock speeds than the ATMega. Atmel devices often have on board peripherals such as I^2C , SPI and ADCs, as well as a number of different memories: Flash, EEPROM and SRAM. An AT32UC3C0512C, ATXmega256A3BU and ATMega644P will be compared in this section.

Table 2.1 shows a brief summary of some common ARM and AVR microcontrollers. The Stellaris offers the most power with the largest DMIPS performance. However, due to the necessity of floating point operations, the AT32 clearly has a distinct advantage by having a built-in floating point unit. The XMega and ATMega do not offer enough power and are restricted by a small amount of SRAM and Flash. All devices looked at use 3.3V supply and have basic communication protocols (SPI, I^2C and USART). Overall, the AT32UC3 is the best choice with a high throughput, a floating point unit and a vast amount of GPIOs and communications. There is no EEPROM which may be desirable, but these can be added onto an SPI or I^2C bus. This device, although slightly more costly, is best suited to this application out of the selection researched.

2.2 Firmware

2.2.1 Camera

The camera used is the OV7670 by OmniVision. Steve Gunn provided source code for use on the Il Matto development board, which streamed video from the camera to a colour TFT screen. The camera is supplied on a small breakout board with a FIFO buffer. The camera operation is discussed in section 3.1. Many implementations of firmware for this camera exist across different devices.

Attribute	ARM Stellaris	AT32UC3C0512C	XMegaA3BU	ATMega644P
Clock Speed (MHz)	80	33 or 66	32	12
DMIPS	100	91	-	20 MIPS
Package	100 LQFP or 108 BGA	64, 100, 144TQFP	64 QFP or QFN	40 DIP, 44 TQFP, 44 QFN
Cost of 1 unit(£)	10.30	15.39	6.65	6.86
Flash Size(kB)	256	512	256	64
SDRAM Size (kB)	32	64	16	4
EEPROM Size(kB)	2	None internal	4	2
GPIO	64	45, 81 or 123	47	32
Operating Voltage (V)	3.3	5 or 3.3	1.6- 3.6 ¹	2.7-5.5
Communication Interfaces	SPI, I^2C , SSI, MAC, CAN, EPI, USB, USART, I2S	SPI, TWI, EBI, USB, Ethernet, CAN, USART, I2S	USART, TWI, USB, SPI	SPI, TWI, USART
Floating Point	None	Built in FPU	None	None
ADCs	16	16	16	8
Timers	4	3 16-bit	7 16-bit, 8 8-bit	2 8-bit, 1 16-bit

Table 2.1: Comparison Table of some common microcontrollers. Data of microcontrollers taken from [Atmel Corporation \(2012a\)](#), [Atmel Corporation \(2012b\)](#), [Atmel Corporation \(2012d\)](#) and [Texas Instruments \(2012\)](#). Costings from [Farnell \(2012\)](#)

2.2.2 Atmel Software Framework

Atmel offer a software framework which contains basic code and device drivers for many of their XMega and AT32 devices ([Atmel Corporation, 2009](#)). There are also many AVR application notes which provide explanations and example code for protocols like I^2C , SPI and timers. These application notes are aimed at older devices like the ATTiny and ATMega. Both the ASF and the application notes are available online and are a good source of code for basic protocols.

Chapter 3

Hardware and Firmware Development

For initial development, the '*Il Matto*' board, designed by Steve Gunn, was used. The system has an ATMega644P, 12MHz clock and an on board SD card socket. This provided the ability to prototype circuits which were then used to create a PCB.

This section is broken down into the following parts:

[3.1 Camera Code](#)

[3.2 SD Card](#)

[3.3 Motor Development](#)

[3.4 PCB Development](#)

3.1 Camera

The camera used is an OV7670 by OmniVision. It is mounted onto a break out board and connected to a AL422B FIFO Buffer. The breakout board has all passive components and a 24MHz clock mounted. The schematic for the device can be seen in appendix B. The camera has a small hardware modification, due to a PCB fault. Pin 8 of the buffer is lifted and connected to pin 6 of the header, which is disconnected from the PCB (see figure [3.1](#)). Original code for the camera

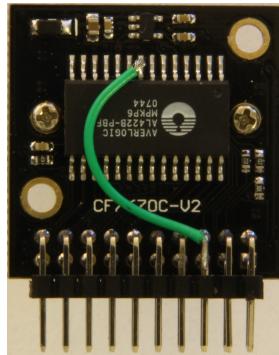

Figure 3.1: Reverse side of the OV7670 Camera showing the modification

operation was given by Steve Gunn which streamed continuous video to a TFT screen from the camera. The operation required was to take a single photo from the camera and store the data.

3.1.1 Single Camera Operation

The camera uses a SCCB Interface ([OmniVision, 2007](#)) created by OmniVision. This is almost identical to the I^2C Interface by Phillips and the two protocols are compatible. The original code for the camera used a software driven SCCB interface which was very slow and used up processing time. This was changed to make use of the built-in interrupt-driven I^2C interface (named TWI in Atmel AVR^s¹). This communication bus is used to write to the control registers of the camera to set up the signals, image format and image size. The set up procedure is used from the code given and sets the camera to function as explained below.

RGB565 is a 16 bit pixel representation where bits 0-4, 5-10 and 11-15, represent the blue, green and red intensity respectively (see figure 3.2). This is a compact way of storing data but only allows 65536 colours. Greys can also appear to be slightly green due to the inconsistent colour ratio of the green field. This representation was used as it is a compact format, easily converted to grey scale and is widely used.

The camera must use a high speed clock in order to ensure the pixels obtained are from the same time. This makes it difficult for an ATMega (typically clocked at 8-12MHz) to be able to respond to the camera quick enough. This highlights the necessity for a FIFO Buffer.

¹ I^2C , SCCB and TWI are all the same but are called differently due to Phillips owning the right to the name “ I^2C ”

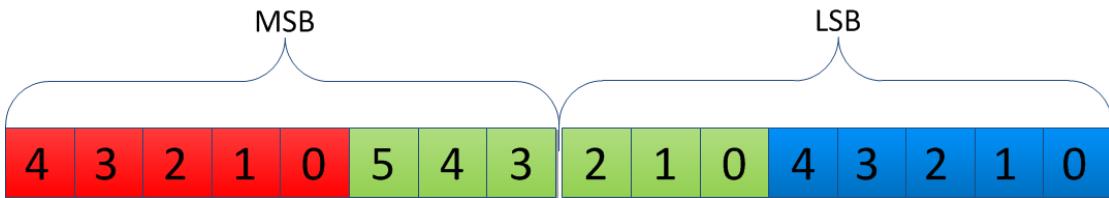

Figure 3.2: RGB565 pixel format

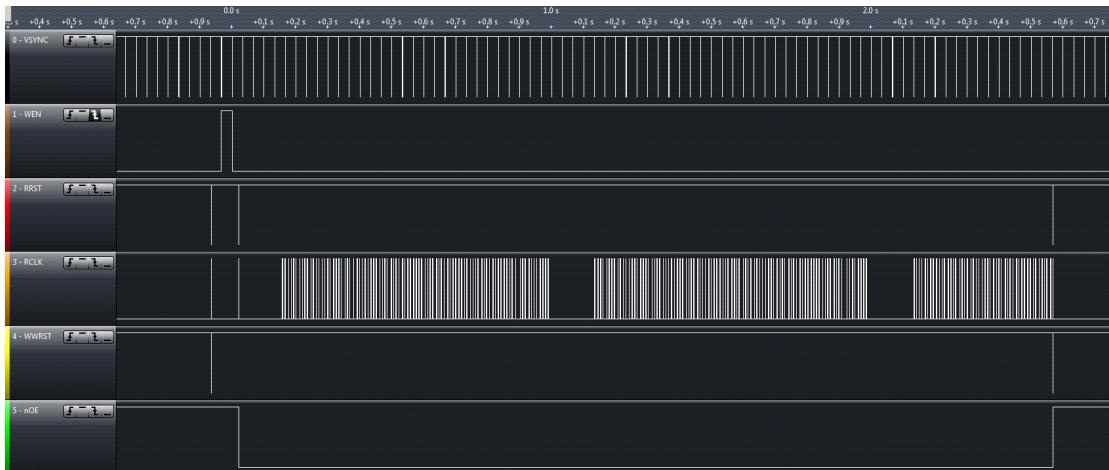

Figure 3.3: Signals generated to control the OV7670 capture and read

The OV7670 is set up so that the VSYNC pin goes low at the beginning of every frame of data, and HREF is high when the data being output is valid. The pixel data is then clocked out on every rising edge of PCLK. To control the buffer, WEN (write enable) is NAND with the HREF signal. When both are high, the write enable to the buffer will be active and the data will be clocked in by PCLK.

In order to acquire a full image, WEN must be high between two consecutive VSYNC pulses. VSYNC is set up to interrupt the AVR and a small state machine is implemented to count VSYNC pulses and control WEN correctly. After the WEN signal is pulsed, the buffer will contain all the valid pixel data.

To obtain the data from the buffer, the AVR sets output enable low and pulses the read clock. Valid data is available on the data port while RCLK is high. All the data is then read half a pixel at a time (the endianness of the data can be set up on the camera).

After the data has been read, the buffer is reset by asserting the read and write reset signals (RRST and WRST) for at least one clock cycle of the relevant clock. The entire operation can be seen in figure 3.3.

Difficulties arose at this point with the storage of the data. The ATMega644P has 4kB of internal SRAM, but 153.6kB of memory is needed to store a single image at QVGA (320 by 240 pixels, 2 bytes per pixel) quality.

Firstly, data was sent to a desktop computer by USART. A simple program was written in C# to receive and store all the data as a Bitmap image. This method was slow, taking around 30 seconds to transmit one uncompressed image.

The second option was to use extra memory connected to the microcontroller. An SD card was used as FAT file system so the memory card is usable on a computer. Text log files were also written to aid debugging. This is discussed in section [3.2](#).

3.1.2 Dual Camera Operation

In order for stereovision to be successful, two cameras separated by a horizontal distance (B) will need to be driven at the same time to obtain photos within a small time frame of one another.

A major problem occurred with using the I^2C interface to set up both cameras. The camera has an I^2C address of 21_{16} , which cannot be changed. Multiple I^2C devices with exactly the same address cannot be used on the same bus. Two solutions to this are possible: driving one from I^2C and one from SCCB, or using an I^2C multiplexer. By using two different buses the cameras will be individually addressable. However, SCCB is slow and processor-hungry as it is software driven. This takes up program memory and is not reusable for other operations.

An I^2C multiplexer sits on one I^2C bus and has multiple output buses. The master can then address the multiplexer and select whether to pass the bus to channel 0, channel 1 or not allow the data to be transferred. This saves processor time, but means a write operation has to be done to select the camera bus before being able to write to the camera. This slows down the operation slightly, but not as much as using SCCB. The main disadvantage to the I^2C multiplexer is the extra hardware needed; firstly the multiplexer itself, but also 7 extra resistors to pull up the two extra buses and the three interrupt lines which aren't used, must be added.

Overall, the disadvantages posed by using a multiplexer are small, so it was used as opposed to the SCCB interface. A suitable multiplexer is the Phillips PCA9542A ([Phillips, 2009](#)).

The buffers have an output enable pin so the data bus can be shared by both cameras to the AVR. The ATMega644P offers three interrupt pins, two of which are used by the two VSYNC pins for the cameras to drive two individual ISRs.

Operation to read an image is identical to using one camera. The code was duplicated so that the two cameras were accessed individually. Care was taken to avoid any bus contention on the data bus, but no checking is explicitly done. When taking a photo, both frames are taken at a time period close together to capture the same scenario. The data can then be read in either order and stored.

3.2 SD Card

To use the SD card, the FATFS library ([Electronic Lives Manufacturing, 2012](#)) was used. The library supplies all the functions for writing a FAT File System in the files *ff.c*, *ff.h*, *ffconf.h*, *diskio.c*, *diskio.h* and *integer.h*. The *diskio.h* functions control what device is being used - SD/MMC Card, USB drive etc. The *ff.h* header contains all the functions to write to in a FAT File system.

An SD card was chosen due to its small size, low cost and a large data storage. The cards work using an SPI bus which can be used for other devices within the system as well.

3.2.1 Storing Images

Many image formats are common, such as Joint Photographic Expert Group (JPEG), Portable Network Graphics (PNG), Bitmap (BMP) and Graphics Interchange Format (GIF). Table 3.1 shows a summary of some common image formats.

It is clear that the best choice for images would be either PNG or JPEG. However, these require more computational time to compress the image into the correct format. To avoid compression, and thereby save processing time, bitmap was chosen at the expense of using more memory. The data in a bitmap image is also stored in RGB format so can be read back easily when processing the image. Appendix F shows the make up of a Bitmap File that was used.

By writing the image in this format, they are then able to be opened on any operating system. This aids debugging and allows the prototyping of image algorithms

	Bitmap	JPEG	PNG	GIF
Extension	*.bmp	*.jpg /*.jpeg	*.png	*.gif
Compression	No	Lossless and Lossy	Lossless ZIP	Lossy
File Size of 320 by 240 pixel Im- age (kB)	225	20	23	24
Bits per Pixel	8, 16, 24 or 32	24	24, 32 or 48	24, but only 256 Colours

Table 3.1: A table comparing different image formats available ([Fulton, 2010](#))

Figure 3.4: An Example Image taken using the OV7670 and stored as a Bitmap on the SD Card

in a more powerful environment. Figure 3.4 shows a photo taken by the OV7670 and stored on a SD card. The quality is not professional, but all features can be seen. The colour is accurate and large text can be read at a small distance.

3.2.2 User Interface

The ATMega 664P pinout for the dual camera operation can be seen in table 3.2. Due to a lack of available GPIO pins, an ATMega168 was added on the I^2C bus

	Port A	Port B	Port C	Port D
0	Data 0	SD Write Protect	I^2C - SCL	No Connection
1	Data 1	SD Card Detect	I^2C - SDA	No Connection
2	Data 2	USB Data Plus	Read Clock 1	VSync 0
3	Data 3	USB Data Minus	Read Reset 1	VSync 1
4	Data 4	SPI Chip Select	Write Enable 1	Read Clock 0
5	Data 5	SPI MOSI	Write Reset 1	Read Reset 0
6	Data 6	SPI MISO	Output Enable 0	Write Enable 0
7	Data 7	SPI Clock	Output Enable 1	Write Reset 0

Table 3.2: Pin Connections of the ATMega644P for Dual Camera Operation.

to act as a port extender. The ATMega168 accepts a read or write command. A write places the written data on Port D and a read returns any button pressed that occurred on Port C. When a button is pressed, this is stored in the ATMega168 until a read has been done. This is so the master (644P) does not miss any button presses while busy doing lengthy operations such as writing an image. The code is based on Application Note AVR311 ([Atmel Corporation, 2007](#)), written for IAR Compiler. This code was altered to compile with GCC under Atmel Studio. AVRs contain a hardware based I^2C protocol that is interrupt driven. The ISR of the TWI vector is a state machine which loads the data to send, stores received data, responds to acknowledges and address calls and deals with bus errors that can occur.

The entire prototype for the dual camera operation can be seen in figure 3.5. This circuit was developed to test the cameras and is used to develop the PCB in section 3.4. Another prototype was also made to stream the camera images to a TFT screen. This helped with testing cameras and focusing them. Figure 3.6 shows the set up during operation.

3.3 Motor Driver Development

3.3.1 Hardware

Tachometers are devices used to measure rotational speed of a shaft. Tachometers are commonly found in bicycles where a small magnet is attached to the wheel and a sensor is attached to the frame. The elapsed time between every rotation

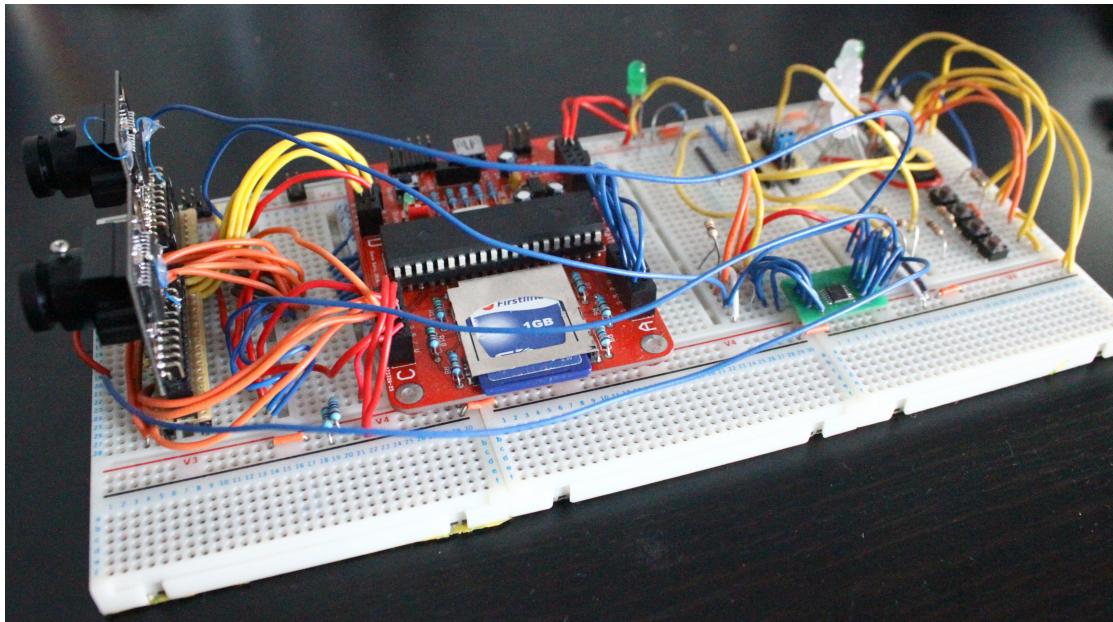

Figure 3.5: Prototype of Dual Camera operation.

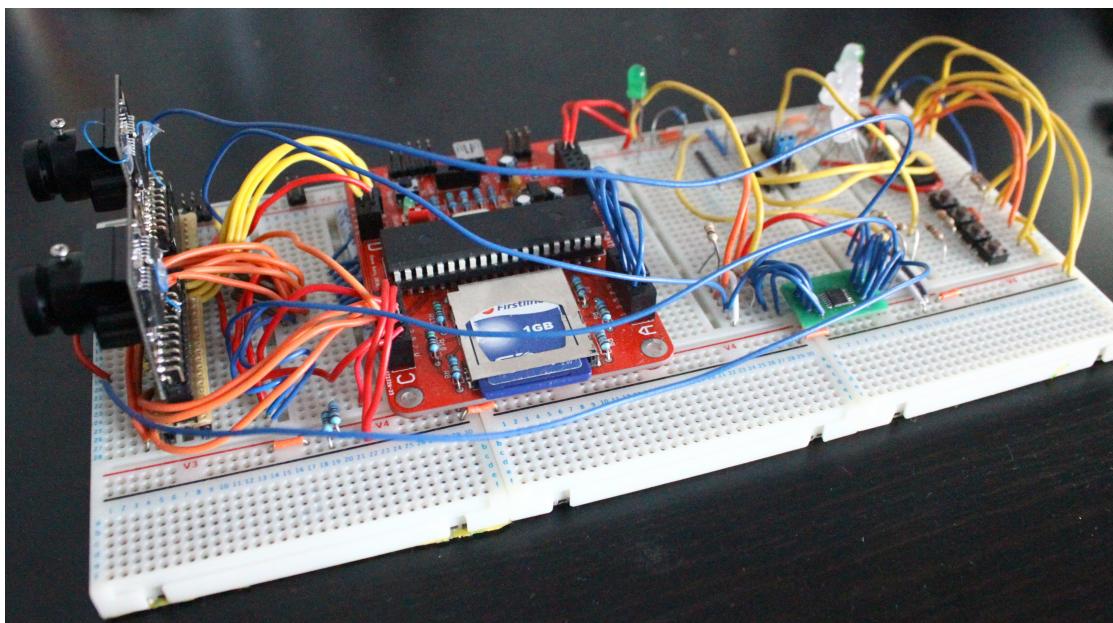

Figure 3.6: Prototype of streaming camera images to TFT screen.

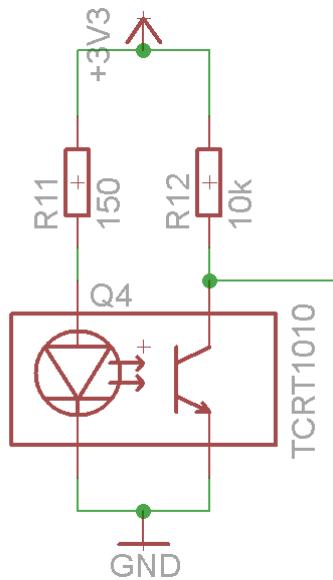

Figure 3.7: Circuit diagram of Optosensor

detected by the sensor is measured and, by knowing the size of the wheel, speed can be calculated.

Here an optosensor, the TCRT1010 made by [Vishay Semiconductors \(2012\)](#), is used to measure rotations of the wheel and used to be able to move a distance determined by the microcontroller. The TCRT1010 package contains an IR LED and a phototransistor. The schematic of a simple transistor amplifier used can be seen in figure 3.7 which was reproduced from [Gunn \(2012\)](#).

A similar method to the way a bike measures speed was used. The wheel's rubber absorbed the IR from the LED, so a high voltage was always seen at the collector of the phototransistor when near the wheel. White tippex marks, "tabs", were applied to the wheels at regular intervals. These tabs reflected IR, resulting in a lower collector voltage and thereby giving a way to detect wheel rotation, but not direction. Figure 3.8 shows the voltage at the collector (read by the ADC on the AVR) against the angle of the wheel. Ten tabs were marked on the wheel, and ten dips in the voltage can be seen in figure 3.8. There is a lot of noise that exists on this line due to the non-uniform white tabs applied. However, the dips are prominent and can be detected with the correct threshold voltage.

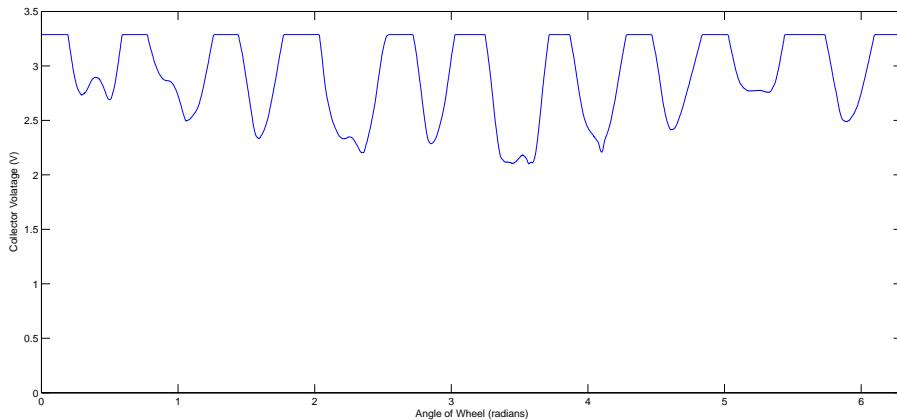

Figure 3.8: Graph of Wheel Angle against the Voltage read by the AVR

3.3.2 Firmware Development

The basic outline of the firmware is a set up to calculate how many counts are needed to move the distance, set the inputs to the motor drivers and use PWM to control the speed. The number of times the tabs pass the sensor are counted and when the count reaches the correct number, the motors are stopped. The robot can move in either a straight line or rotate on the spot. More complex movements, for example arcs, would require more accurate tachometers and are not discussed here.

Moving in a straight line takes a parameter of how far to move as a signed integer and calculates the total number of counts that need to occur. This can be calculated using equation (3.1). This value is put in a global variable so that other methods have scope to it.

$$\text{Counts} = \delta \times \frac{\gamma}{C_w} \quad (3.1)$$

For rotation, the radius from the centre of the robot to the wheels needs to be known, see figure 3.10(a). The circumference through the wheels is then easily calculated and the angle of rotation is then a ratio. The distance to move is calculated by equation (3.2) and the total number of interrupts can be calculated using equation (3.1). To rotate clockwise, the left motor is driven forward and the right is driven backwards. To rotate anti-clockwise, the directions are reversed.

$$\delta_R = A \times \frac{C_b}{360} \quad (3.2)$$

Combining equations (3.1) and (3.2) gives:

$$\text{Interrupts} = A \times \frac{\gamma}{C_w} \times \frac{C_b}{360} \quad (3.3)$$

Where A is the angle to rotate in degrees, γ is the counts per revolution of the wheel, C_w is the circumference of the wheel and $C_b = 2\pi \times r_b$ and r_b is the distance from the centre of the robot to the centre of the wheel (see figure 3.10).

As the voltage swing on the collector of the phototransistor does not reach near 0V, the AVR cannot detect this as a logical 0. An external amplifier could be used to generate a full swing voltage. However, the AVR has ADCs and analogue comparators.

The ADC could be used to continually sample the collector voltage and detect dips in the signal. This method has the advantage of a variable threshold and the ability to filter noise. The operation, however, would be complex to implement in code.

An alternative is to use an analogue comparator. The UC3C has two on chip comparator interfaces, each with two comparators. They are a high gain operational amplifier with added options of hysteresis and the ability to interrupt amongst other attributes. The comparators can use two analogue inputs or use the internal DACs as inputs. Potentiometers were used to set the reference voltage externally. This method has the advantage of returning a boolean value of if the collector voltage is higher or lower than the threshold voltage. The detection is easier to detect than reading ADC values and the code will be simpler to implement. This method was decided on for an easier implementation.

The first method implemented was to use the analogue comparators to interrupt when the collector voltage crossed the threshold. Both wheels used the same comparator interface and therefore ran the same ISR when triggered. The ISR then had to read the output of the comparators and decrement the relevant counter for the correct wheel. This method had many downfalls. First, it was not possible to know which comparator caused the interrupt. If the left wheel triggered the interrupt while the right was below the threshold, both left and right counters would be decremented. This caused a large error each time it occurred. Another problem was noise; occasionally, the lowering voltage would cause multiple interrupts each time. This problem was reduced by setting the hysteresis on the comparators but did not solve the problem completely.

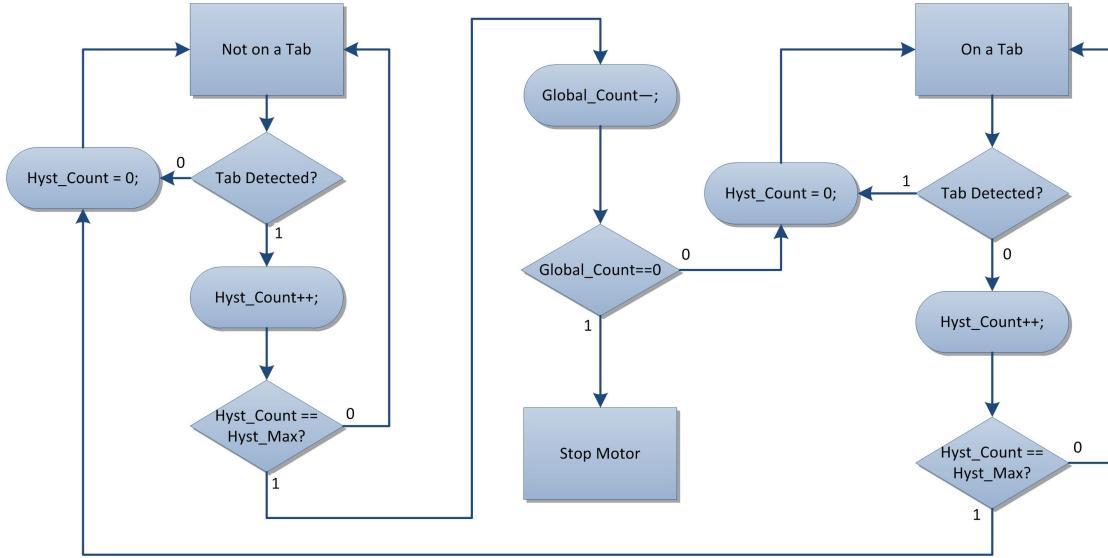

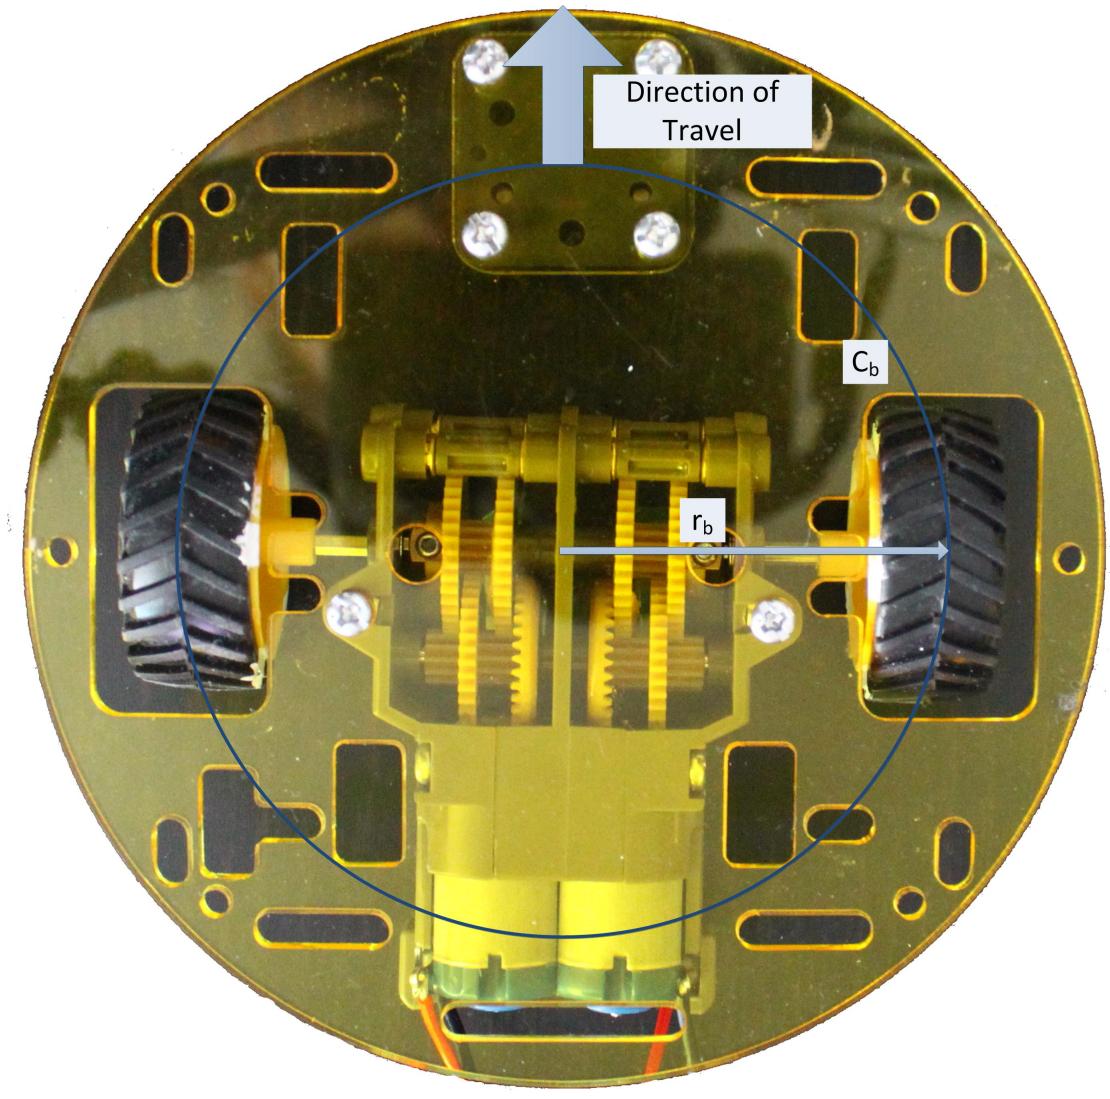

Figure 3.9: A State Machine showing the operation of the *Motor_Execute* method

A second approach utilised a simple state machine and software based hysteresis to solve the problems. After the set up is complete, the method *Motors_Execute* is run, containing the state machine to control the motors. The state machine has two states ‘On a Tab’ and ‘Not on a Tab’. When the method enters, the initial state is read from the comparators. If the wheel is already on a tab, it won’t be counted. The code then runs in a loop until the motors stop. A graphic representation of the code can be seen in figure 3.9. Starting in ‘Not on a Tab’ state, a tab must be detected for *Hyst_Max* cycles in succession for the state to change. This is the same for going from ‘On a Tab’ to ‘Not on a Tab’. This is to reduce noise in the form of false readings and increase the certainty that a tab is in detect. The *Global_Count* is only reduced on the transition to ‘On a Tab’ so it is difficult for this to decrement multiple times in normal operation. To increase the certainty, *Hyst_Max* can be increased at the expense of response time.

The motor speed was controlled by PWM. The code sets up a low duty cycle PWM signal to drive the motors slowly. This causes any overshoot that could happen to be low and removes the need for a speed controller.

The final code can be seen in appendix H. *Motor_Init* method must be called before operation can occur. This sets up the PWM and analogue comparators. Methods *Motors_Move* and *Motors_Rotate* are the methods that can be called to move in a straight line or rotate on the spot. They both take an input which is a signed integer of either the distance to move (in millimetres) or the angle to rotate

(a) Top View of robot base showing dimensions of interest

Figure 3.10: Dimensions of Interest for Robot Movement

Table 3.3: Results of Motor Distance Test

Distance Specified (mm)	Number of Counts Returned	Counts \times Resolution (mm)	Average Measured Distance Moved (mm)	Error (%)
50	4	46.4	47.25	1.83
75	6	69.6	70.75	1.65
100	8	92.8	97.0	4.52
120	10	116.0	113.25	2.37
150	12	139.2	141.0	1.29
170	14	162.4	161.5	0.55
200	17	197.2	201.5	2.18
250	21	243.6	244.5	0.37
300	25	290.0	290.75	0.26

(in degrees, and positive is a clockwise movement). They both return the actual movement distances, due to the low resolution of the system.

3.3.3 Testing

Test Rotation

To test the motor system, different distances were given to the movement method. The method prints how many counts will be moved. The actual distance moved was then measured and repeated four times. Table 3.3 shows the results of this test and figure 3.11. The results show that the maximum error observed is 4.52%, which related to 4.5mm. This error is acceptable as a half centimetre error over 10 will not impact the performance of the robot. The error is calculated from the actual distance predicted to move.

A problem was seen that the robot moved in a slight arc. Speed tests were done on the wheel by measuring the total time taken to complete eight full revolutions, the equivalent of moving 928mm. The results and the calculated wheel speeds can be seen in table 3.4. It shows that the left motor runs slightly faster than the right, even though the PWM duty cycle is the same. A controller could be implemented to correct this error during operation. However, over the distances covered, the error introduced by this is small enough to neglect.

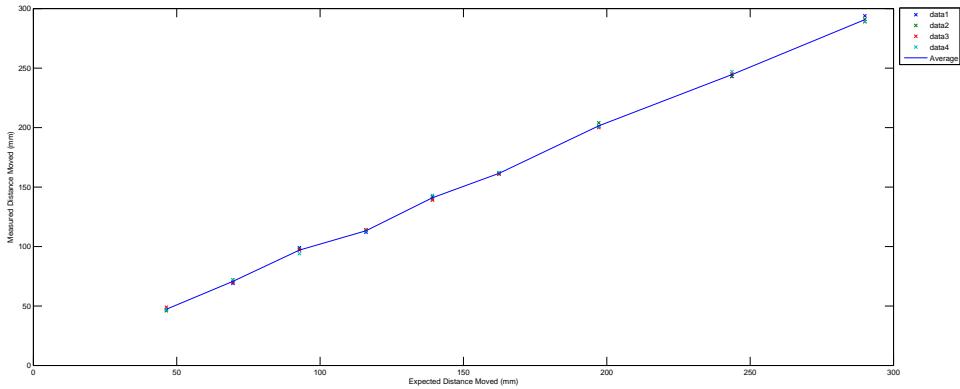

Figure 3.11: A plot of Expected Distance against the measured data. Line indicates the average of the data at each point.

Table 3.4: Results of motor speed test

Wheel	Total Time Elapsed (s)	Calculated Speed ($mm.s^{-1}$)
Left	44.6	20.8
Right	49.6	18.7

3.3.4 Conclusion

Due to the low resolution of the sensor (10 counts per revolution), there is a minimum distance that can be moved and a minimum angle of rotation, shown in equations (3.4) and (3.5) respectively. These show that greater distance resolution can be obtained by decreasing the wheel size or increasing γ and a greater rotational resolution can be obtained by the same as distance, or by increasing the distance the wheels are from the centre of the robot. The ratio $C_w : \gamma$ should be as large as possible to obtain the best resolution for movement.

$$\Delta_\delta = \frac{C_w}{\gamma} = 12mm \quad (3.4)$$

$$\Delta_\theta = \frac{360 \times C_w}{\gamma \times C_b} \approx 15^\circ \quad (3.5)$$

This method lacks on two points - lack of speed control and accuracy. A better controller could be implemented to help move at different speeds. This could use the remaining number of counts to gradually slow the speed of the motors down proportionally as well as correct the speed mismatch between the wheels. A PID controller could be implemented if greater accuracy is needed quicker, at the expense of computation time and potential overshoot.

Rotary encoders could be used to detect the direction of wheels as well. A good, but more costly, alternative would be the HUB-ee wheel by [Creative Robotics Ltd \(2013\)](#), which includes a 120 point quadrature encoder and sensor, motor driver and a geared motor all within the wheel. These wheels have 12 times the accuracy as the method described here and a similar interface.

Given that the robot does not need to move any more accurately than to 1cm, this method has proved to be cheap and successful. The robot is able to move a distance with reasonable accuracy, but to a fairly low resolution.

3.4 PCB Development

3.4.1 Circuit Design

Figure [3.12](#) shows a basic hierarchy of the robot. Each pin on the AT32UC3C0512C can have one of up to six special functions, as well as being a GPIO pin. Table [3.5](#) shows the pinout for the microcontroller used.

The circuit diagram for Revision A can be seen in section [B.3](#). The schematic for the SDRAM and values and locations of decoupling capacitors were used from the schematic of the UC3C-EK development board ([Atmel Corporation, 2012c](#)).

3.4.2 PCB Design

The PCB was designed using EAGLE CAD Software. A four layer board was decided to be used to reduce the number of tracks and more easily supply power and ground to the devices. Layer two is a 3V3 plane and layer three is a ground plane. A ground plane is also on the top and bottom layers to help eliminate any ground bounce that could occur.

The SDRAM uses the EBI protocol. In high speed systems, care is often taken to equalise track lengths ([Liu and Lin, 2004](#)). The UC3C maximum clock frequency is 33MHz (with no wait states), which is not fast enough to cause any track equalisation problems. Care, however, was taken on the USB lines to ensure correct impedance and the tracks lengths matched to each other.

Tracks were routed in order of priority, starting with the UC3C, SDRAM and cameras. All other devices were then routed (I^2C MUX, SD card, motor drivers

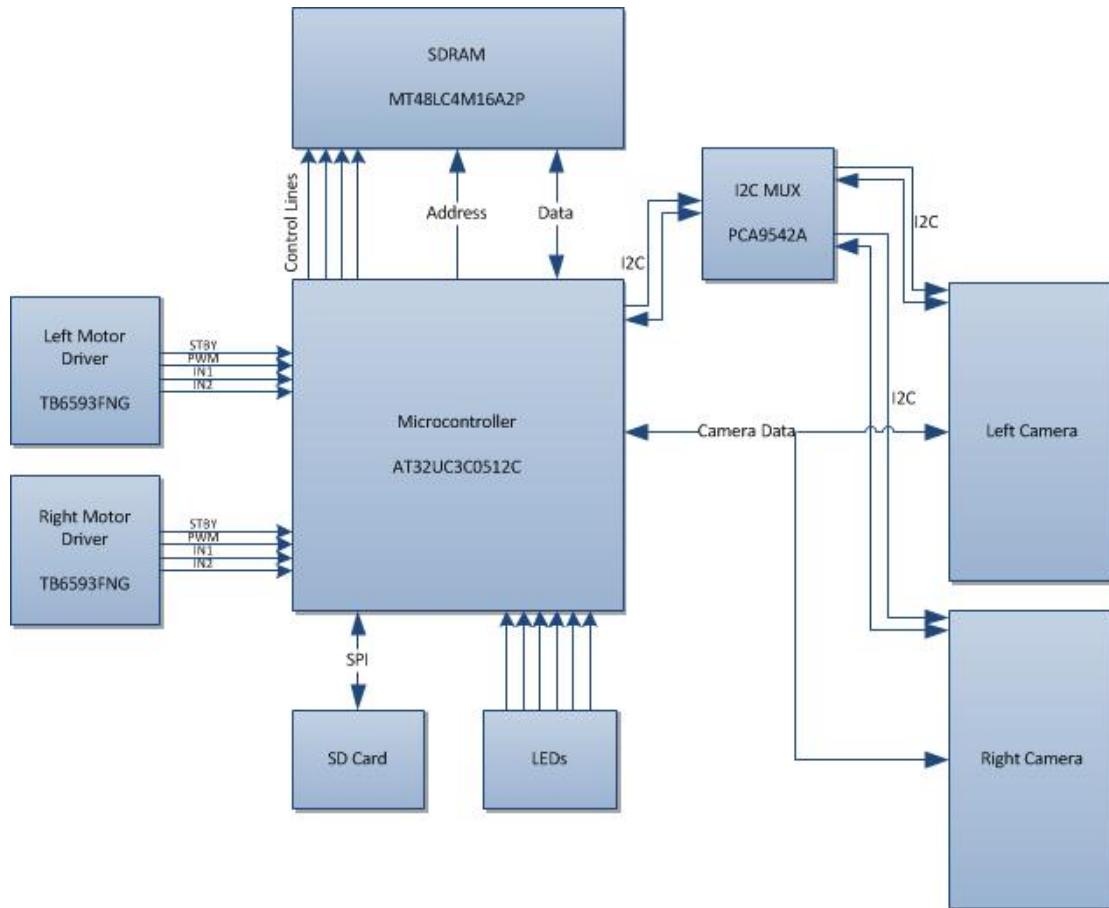

Figure 3.12: A hierarchical diagram of the robot

etc). As a precaution, spare pins from the UC3C were routed to a header (J8 and J9) so that additions could be done if a pinout or connection was found to be incorrect. UART, I^2C and SPI connections were routed to headers J7, J4 and J5 respectively so logic analysers and COM Port could be attached easily for debugging, or so that extra devices could be added onto the respective protocols for future developments.

Passives used were all surface mount of either 0603 or 1206 size to save space on the board. All headers used were 0.1" spaced for easy connections and a mini B USB socket was added for either power or so that the robot can act as a USB device.

The layout of components was important. The cameras needed to be as far apart as possible and at the front of the PCB. The motor drivers were situated toward the back of the PCB and headers were added to connect the motors to. The optosensors were positioned such that they could be mounted directly on the PCB and be in the correct position to sense the wheels. Mounting holes were also added

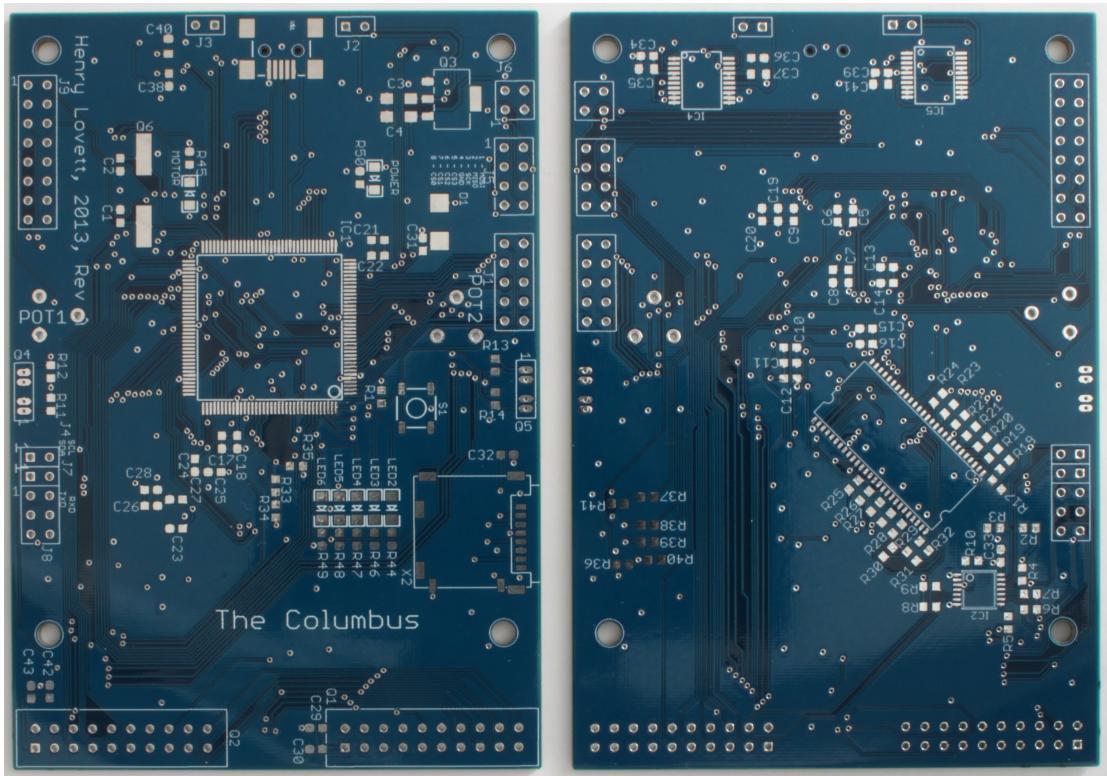

Figure 3.13: PCB with no components. Left: Top View. Right: Bottom View

onto the board so the PCB could be mounted on to the robot base easily. The overall dimensions of the PCB were $100\text{mm} \times 70\text{mm}$. A full list of components and cost of each is documented in Appendix D

Finally, the name “The Columbus” was decided on as the original application for the project was a mapping robot that would search out an unknown area, so the robot was named after Christopher Columbus who explored and navigated parts of the American continents which were unknown at the time. The Eagle CAD Diagram of the PCB can be seen in Appendix C. The PCB was manufactured by [Cart \(2013\)](#). The PCB cost £205 to manufacture and ship. A photo of the PCB can be seen in figure 3.13.

Considerations - Power consumption of devices not exceeding VReg

3.4.3 PCB Testing

A program was written to test all the devices on the PCB. The following tests are done and are explained in the subsequent sections:

3.4.3.1 UART Send and Receive

3.4.3.2 SD Card

3.4.3.3 LEDs

3.4.3.4 SDRAM

3.4.3.5 I^2C

3.4.3.6 Camera

3.4.3.7 Motor

3.4.3.1 UART Test

When the test program begins, the microcontroller waits for a character input. All characters are echoed back. This enables the user to check the communications work. Once a carriage return key is received (D_{16}), the test program continues. Listing 3.1 shows the test code for the UART protocol.

Listing 3.1: UART Test Code

```

1 ///////////////////////////////////////////////////////////////////
2 // UART Test ///////////////////////////////////////////////////////////////////
3 ///////////////////////////////////////////////////////////////////
4 uint8_t ch;
5 while (true) {
6     ch = usart_getchar(DBG_USART); // get one input character
7     if (ch) {
8         print_dbg(ch); // echo to output
9     }
10    if(ch == 13)
11        break;
12 }
```

3.4.3.2 SD Card Test

The Atmel Software Framework ([Atmel Corporation, 2009](#)) provided drivers and code for SPI communications and use of a FAT32 File System. The code was configured to use the correct Chip Select pin for the SD Card and the correct SPI Bus. The test consists of initialising the memory, reading the capacity of the card and printing it to the user.

The AVR then proceeds to delete any previous log file, create a new log file and writes “*Columbus Tester*” to it. The first 8 characters, which should be “*Columbus*” are read back and checked.

Listing 3.2: UART Test Code

```

64     if(Buffer[6] != 'u')
65         noErrors++;
66     if(Buffer[7] != 's')
67         noErrors++;
68     file_close();
69     if(noErrors == 0)
70         print_dbg("\n\rSD Card Read Successful\n\r");
71     else
72         print_dbg("\n\rSD Card Read Fail\n\r");
73     noErrors = 0;

```

This exercises all basic File I/O functions, creating, reading and writing and checks them on the device.

3.4.3.3 LED Test

All LEDs are turned on for 1 second, and then turned off. The user should check this occurs. It verifies that all the LEDs are functional and correctly mounted. The Power LED should be on when power is supplied to the PCB.

3.4.3.4 SDRAM Test

The SDRAM test consists of initialising the SDRAM, calculating the SDRAM size, writing a unique test pattern to the whole memory, and then reading it back and checking it. The total number of errors are reported.

The test was adapted from an example application from the ASF ([Atmel Corporation, 2009](#)). The code can be seen in listing 3.3. It consists of two *for* loops. In the first, the iteration number is assigned to the memory location. The second loop reads back the data and checks it is correct. An int, *noErrors*, is used to count errors.

Listing 3.3: SDRAM Test Code

```

34    if (tmp != i)//failed
35    {
36        noErrors++;
37    }
38 }
39 print_dbg("\rSDRAM tested: ");
40 print_dbg_ulong(noErrors);
41 print_dbg(" corrupted word(s)      \r\n");
42

```

3.4.3.5 I^2C Test

The I^2C test checks the bus for devices. It prints out a table showing the address of any devices that acknowledge a probe. A probe is a set up to write to the address. If a device exists on the line, it should acknowledge (Phillips, 2012). The test is done three times, with no channel selected on the I^2C MUX, with channel 0 selected and with channel 1 selected. The two addresses expected at 21_{16} for the

OV7670 Camera and 74₁₆ for the I^2C MUX. The camera should only acknowledge when the I^2C MUX has the relevant channel selected. Listing 3.4 shows the test code for the I^2C bus and listing 3.5 shows the result from the full bus scan with channel 0 selected. The cameras are both checked to exist.

Listing 3.4: I^2C Test Code

3.4.3.6 Camera Test

This test consists of initialising both cameras and checking it passes. Two photos are then taken and stored to the SD card. Success or failure of the methods is sent to the debug terminal. Two images should exists on the SD card from the two cameras. Listing 3.6 shows the code to conduct this test.

3.4.3.7 Motor Driver Test

An extensive test of the motor driver is discussed in section 3.3.3. The test code in this application resets the motors so that they are aligned to a white tab on the wheel. This code can be seen in listing 3.7. The robot should move no further than 1cm to reach a white tab and the motors should drive forward. This test is useful here to ensure the motors are connected the correct way around and that the potentiometers are set to an appropriate level.

8     ;//wait for the motors to finish moving

```

3.4.4 PCB Faults

During the build and test of the PCB, a number of faults were found. Each is explained and the solution for the problem given.

3.4.4.1 TCRT1010 Footprint

The holes in the footprint for the optosensor were not large enough. This was a minor problem as the sensor was soldered in a surface mount style. This didn't affect the location of the sensor so had no other implications other than the connection being weaker than it should be.

3.4.4.2 SDRAM Footprint

The SDRAM footprint made was done exactly to the specification of the pad size and locations with no consideration for soldering. This meant the chip fits exactly on to the footprint and made soldering difficult as pads had to be preloaded with solder and the device's pins were heated and bound to the solder. It also put the device at risk as more heat had to be used than usually necessary. Figure 3.14

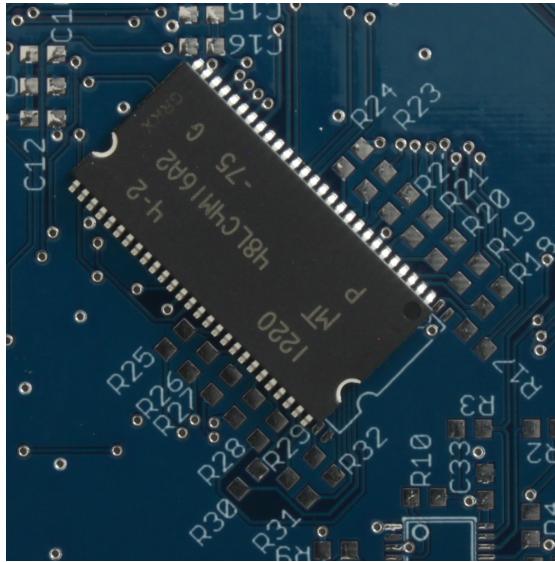

Figure 3.14: SDRAM Chip shown against its footprint.

shows the SDRAM chip slightly offset against the footprint. It can be seen that there is no extra space on the pad to be able to easily solder the device. Though this made building difficult and increased soldering errors, it had no impact on the operation of the device.

To avoid this, existing footprints could be used from other libraries, or double checking the footprints made. The problem meant extra care during soldering had to be taken but has not impeded the operation of the device.

3.4.4.3 SDRAM Chip Select

The code was prototyped on the Atmel UC3C-EK development board prior to the PCB arriving. This used chip select 1 for the SDRAM and the PCB was designed using chip select 0. When the PCB was built, the code did not work. To diagnose this problem, the control lines of the SDRAM were probed with a logic analyser. On the UC3C-EK, the bus was busy with refresh cycles outside of SDRAM access. On the Columbus, no activity was seen.

The reason the correct control wasn't being seen was due to the UC3C device having a dedicated SDRAM controller, attached only to chip select line 1. Chip select 1 was available on an external pin, and the via on the CS0 and CS1 lines were close to each other. Therefore, to overcome the problem, a small enamelled wire was soldered to join the two vias together. This solved the problem and the

correct signals were then seen on the control lines. The patch can be seen in figure 3.16(b).

This fault was caused by not reading the datasheet carefully and ignoring a proven circuit diagram. Operation of the device was not hindered and the fix was simple.

3.4.4.4 SDRAM Data Line Resistors

Once the chip select problem was solved, data returned was unreliable. The SDRAM is word (32 bit) addressed, but accessed in 16 bits. This means read cycles are done per word read. Upon investigation of this problem, the 14th, 15th, 30th and 31st (top two bits of each 16 bit access) seemed to read as a 1 the majority of the time. This result wasn't repeatable and sometimes returned correct data. The other bits of the data were always correct. Table 3.6 shows some examples of the problematic data bits. The data written should match the data read back.

Table 3.6: A table showing examples of the incorrect data returned from the SDRAM

Data Written	Data Read
00000000 00000000 00000000 00000000	11000000 00000000 11000000 00000000
00001111 00001111 00001111 00001111	11001111 00001111 11001111 00001111

The problem was traced to resistors **R31** and **R32**. They were soldered on incorrectly so that the two data lines of the SDRAM were connected together and the two AVR GPIO pins were connected together. Data was then read back from, effectively, a high impedance line and therefore varied. Once the resistors were soldered correctly, the issue no longer persisted and the whole SDRAM test passed. By utilising the soldermask more, device orientations could be added to ensure correct placement. This can be extended to other devices, such as diodes and capacitors, especially in densely populated areas.

3.4.4.5 Camera Interrupt Line

As discussed in section 3.1, the OV7670 needs an interrupt line to synchronise quickly to the start of the frame and is done by using an interrupt line. The UC3C0512C has 9 external interrupt lines. On the PCB, interrupt lines 0 and 1 were used for this control.

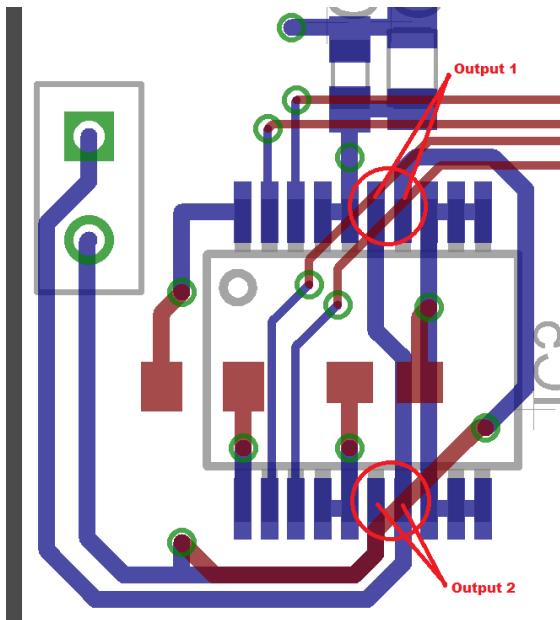

Figure 3.15: Motor Driver error. Outputs incorrectly connected

Interrupt line 1 was easily configured and worked as expected. However, interrupt 0 did not seem to trigger the interrupt service routine. It was found that interrupt 0 was a “Non Maskable Interrupt” which has specific uses and cannot be used in to trigger a method.

The external interrupt 4 pin was wired to Junction 8 on the PCB. A wire was attached to the camera’s VSYNC line and attached to the relevant pin on the header. The operation was then easily obtained and the VSYNC line triggered correctly.

This issues would have been avoided with more understanding of the device before hand and checking the datasheet. The patch can also be seen in figure 3.16(b).

3.4.4.6 Motor Driver Pinout

An error was made in creating the device for the TB6593FNG Motor Driver in EAGLE. On the device, each motor output has two pins to drive each pin of the motor. The pin assignment was mixed up when created and connected the two outputs together. Figure 3.15 shows the track errors on one of the motor drivers.

To solve this, pins 7 and 14 were lifted and removed so that output 1 and output 2 were not connected together. The devices were not damaged in the process of testing this and the motors functioned correctly after this. Double checking the footprints made against the datasheet would have avoided this problem. No

impact to the operation of the drivers has been seen, but the patch may hinder the devices ability to sink current to the motors.

3.4.5 PCB Conclusions

A number of faults were made in the PCB design. They are:

- TCRT1010 footprint
- SDRAM footprint
- SDRAM chip select line
- SDRAM data line resistors
- Camera interrupt line
- Motor driver pinout

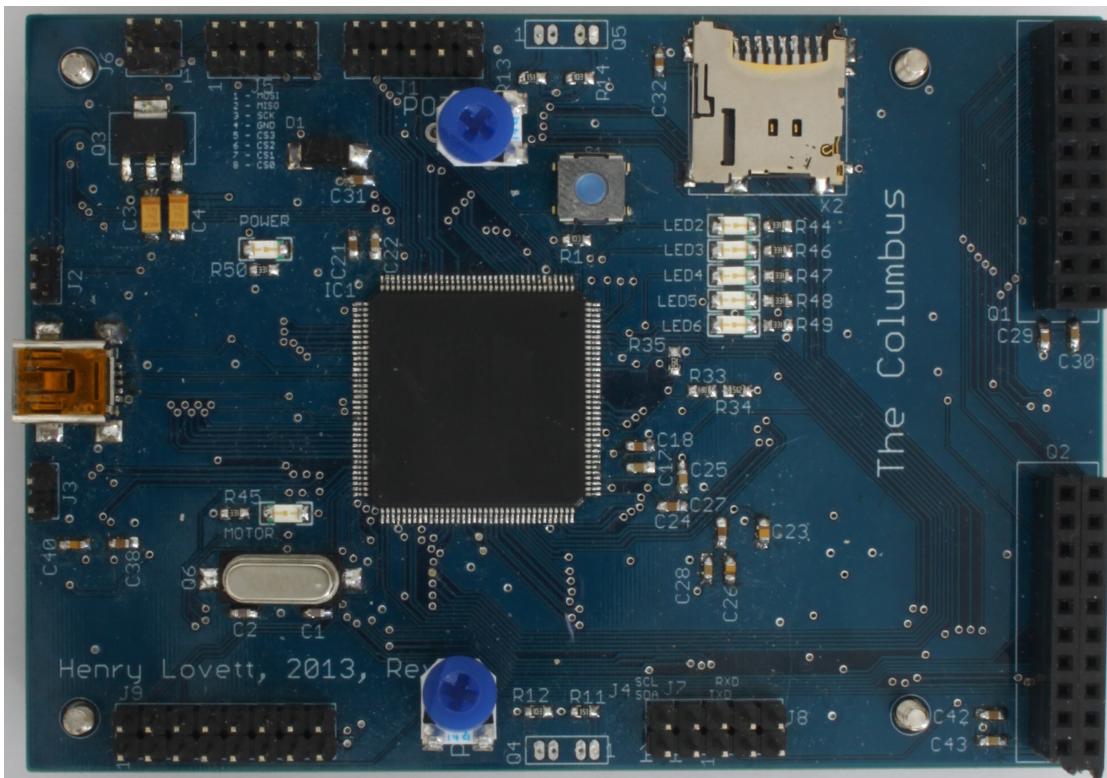

Three of the faults could have been avoided by consulting the datasheet more carefully during the circuit design stage. The footprint error was due to not being experienced in designing footprints and the data line resistors was a mistake due to lack of attention being paid.

For future PCBs, more care will be taken in circuit design, with prototyping of circuits with the hardware that will be used. This will highlight any pin specific operations (e.g. the non maskable interrupt) and reduce debugging post production. The effectiveness of a soldermask is also apparent, so more time spent on utilising this would be helpful during assembly.

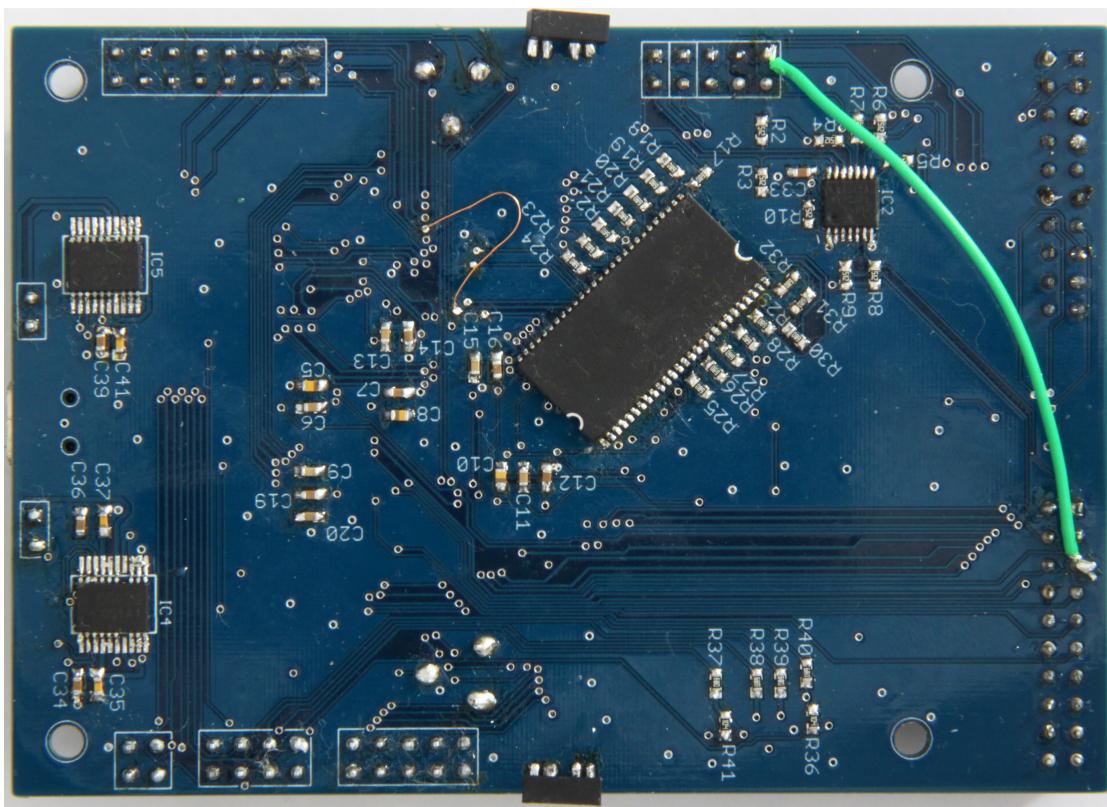

The PCB itself, was a success. It was a complex PCB with many potential things that could have gone wrong. All devices are functional (with a few small modifications) on the PCB so firmware development could continue with all hardware able to be used.

3.5 Conclusions

Overall, the hardware design and firmware is a success. A few minor faults were apparent on the PCB, but these were easily patched and caused no problem. Using

(a) Top view of built PCB

(b) Bottom view of built PCB with SDRAM chip select patch

Figure 3.16: Pictures of the built PCB.

a firmware test, the components are seen to be fully functional giving the UC3C full ability to control motors, cameras, I^2C multiplexer, memory of both SD card (up to 2GB size) and external 4MB RAM. This provides a good platform for a manoeuvrable, stereoscopic image robot to be developed.

Chapter 4

Investigation into Vision Algorithms

4.1 Matching Algorithms

In computer vision, there are many different ways of comparing two similar images. These include the sum of absolute differences (S.A.D.) ([Hamzah et al., 2010](#)), the sum of squared differences (S.S.D.)([Mrovlje and Vrančić, 2008](#)) and normalised cross correlation (N.C.C.)([Zhao et al., 2006](#)). Each of these methods will be explained and tested to compare them. All testing will use images seen in figure 4.1. Each test uses the same size window (50×50) to compare the two images.

(a) Left Image

(b) Right Image

Figure 4.1: Stereoscopic Test Images from MATLAB Examples

4.1.1 Sum of Absolute Differences

Given two identically sized two dimensional matrices, A, B , of dimensions I, J , SAD is defined as

$$SAD = \sum_{i=0}^{I-1} \sum_{j=0}^{J-1} |A[i, j] - B[i, j]| \quad (4.1)$$

This method subtracts the observed window from the expected. All differences are then added together. This algorithm is simple and requires a small amount of computation. The algorithm returns values where a small result means the two images are well matched.

4.1.2 Sum of Squared Differences

$$SSD = \sum_{i=0}^{I-1} \sum_{j=0}^{J-1} (A[i, j] - B[i, j])^2 \quad (4.2)$$

This is very similar to S.A.D. but adds more complexity by squaring each difference. This removes the ability of equally different but opposite differences cancelling each other out (grey to white of one pixel will cancel out a white to grey difference in the other with SAD). Again, a low result is a match in this case.

test effect of box size?

4.1.3 NCC

$$NCC = \frac{1}{n} \sum_{i,j} \frac{(A[i, j] - \bar{A})(B[i, j] - \bar{B})}{\sigma_A \cdot \sigma_B} \quad (4.3)$$

Where n is the number of pixels in A and B ,
 σ is the standard deviation of the image, and
 \bar{A} is the average pixel value.

NCC is very similar to cross correlation, but normalised to reduce the error if one image is brighter than the other. This is common in computer vision ([Tsai and Lin, 2003](#)) and cross correlation is often used in digital signal processing, so fast algorithms have been made to calculate this.

Unlike S.S.D. and S.A.D., the normalised cross correlation gives a high value for a match. The downside to this algorithm comes with the complexity of the equation as it contains division and the square root of a number in order to calculate the standard deviation. These operations are rarely implemented in hardware and are time consuming to carry out in software. They also require floating point registers and operate slowly on a microcontroller without any.

4.1.4 Comparison

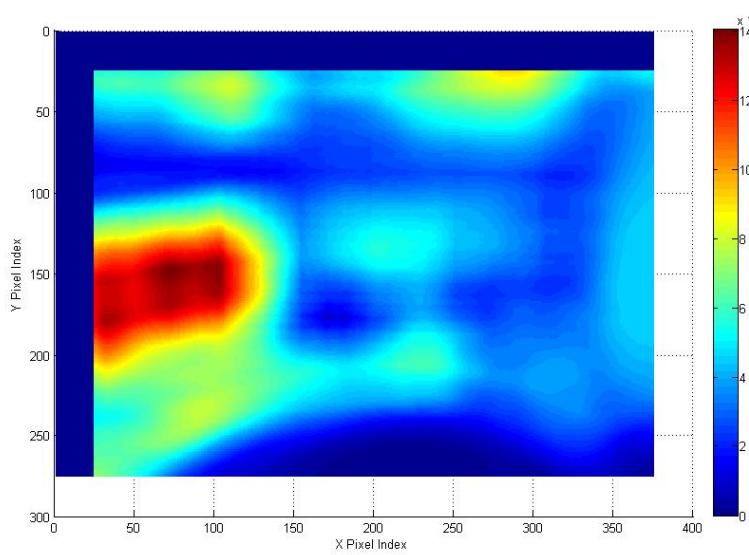

To compare these equations, a 50×50 template taken from the right picture was compared with the left image over the entire valid range. The coordinates on the graph give the centre pixel of the calculation.

Each graph shows the correct area being identified as a match, but this also highlights the downfalls of the SAD and SSD. The figures in figure 4.2 are rotated to match the orientation of the images in figure 4.1. Each of the images is tested by attempting to match the desk phone from the right image to the entirety of the left image. The actual match should be around (170, 176). An exact result cannot be estimated as the images are not matched perfectly - there isn't an exact integer of pixel difference between the images. This is the sub pixel problem ([Haller and Nedevschi, 2012](#)).

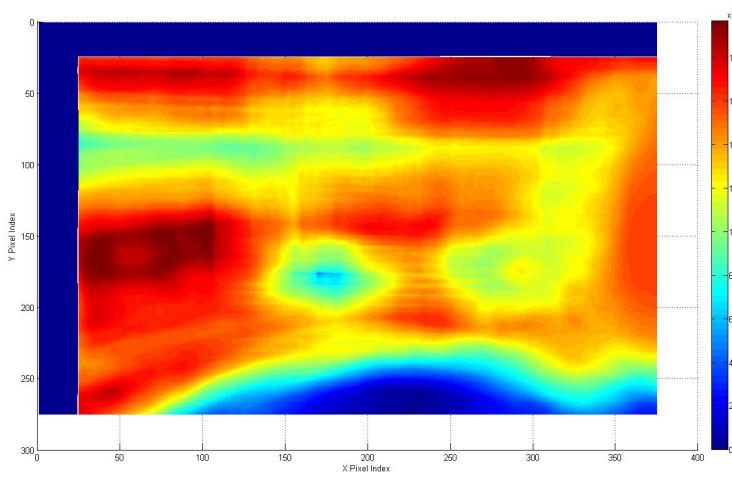

SAD results in figure 4.2(a) show large areas of matching. A minimum occurs around the location expected(170, 175) of a value of 5.66×10^4 . However, along the bottom of the image, where a dark area occurs below the desk in the lower part of figures 4.1, the SAD algorithm detects a greater comparison, with the lowest value in this area being 3370 at (227, 275). This creates a false detection here.

SSD, figure 4.2(b), shows matches in the same two areas: where a match should occur and the dark area beneath the desk. The minimum value where the match should occur is 4.355×10^5 at location (170, 176). However, there is a large match correlation between the dark area under the desk where the actual lowest value of 2.768×10^4 occurs at (225, 274). This, again, is a false match and is a downfall of this algorithm.

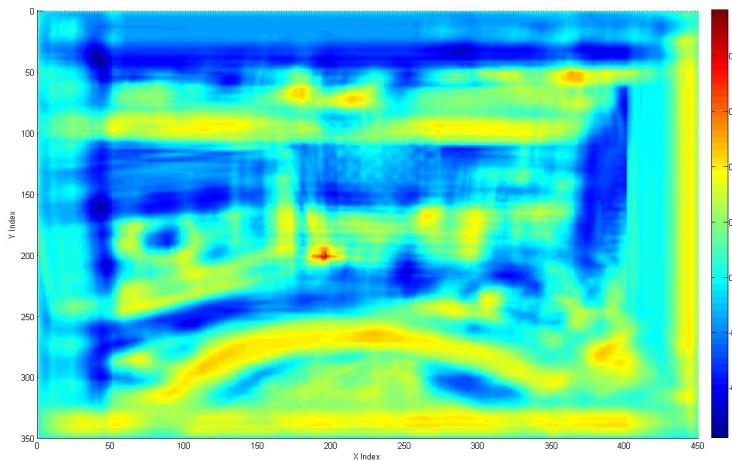

The NCC results are visible in figure 4.2(c). A match can be seen at coordinate (195, 201) with a peak value of 0.9654. The coordinate is different to the previous results because the cross correlation works over the boundary of the image creating more results. The dimensions of the image are 300×400 , but the NCC returns

(a) S.A.D. Results (Low match)

(b) S.S.D. Results (Low match)

(c) N.C.C. Results (High match)

Figure 4.2: Result Graphs of Comparison Algorithms

an data set of dimensions 350×450 when using a template size of 50×50 . To get the actual match, half of the box size must be subtracted from the returned coordinate. This means the match occurs at $(170, 176)$. With this algorithm, there is no area of the image which is close to a false detection.

4.1.5 Conclusion

It can be seen that there is a direct correlation between the complexity of the matching algorithm to the reliability of the match returned. In brightly lit, colourful environments absent of dark colours, SAD and SSD should provide a reliable result, but this cannot be guaranteed to always be the case. Therefore further development of the matching algorithm will start with using the normalised cross correlation. A comprise between complexity and reliability needs to be reached, where reliability is the more desirable of the two. Cross correlation is also a large area of research, so optimised algorithms do exist.

4.2 Range Finding

4.2.1 Derivations

By using two images separated by a horizontal distance, B , the range of an object can be found given some characteristics of the camera. Appendix G contains the derivations for the follow scenarios:

1. Object is between the cameras (Figure G.1)
2. Object is in left or right hand sides of both images (Figure G.2)
3. Object is directly in front of a camera (Figure G.3)

4.2.2 Summary

There are three situations that can occur. These are listed below with their equations.

Object is between the two cameras:

$$D = \frac{Bx_0}{2 \tan\left(\frac{\varphi_0}{2}\right)(x_1 - x_2)} \quad (4.4)$$

Object is to the same side in both images:

$$D = B \cdot \frac{\cos(\varphi_2) \cdot \cos(\varphi_1)}{\sin(\varphi_2 - \varphi_1)} \quad (4.5)$$

Object is directly in front of a camera:

$$D = B \tan\left(\frac{\pi}{2} - \varphi_2\right) \quad (4.6)$$

Where φ_1 is defined in equation (4.7) and φ_2 is defined in equation (4.8).

$$\varphi_1 = \arctan\left(\frac{2x_1}{x_0} \tan\left(\frac{\varphi_0}{2}\right)\right) \quad (4.7)$$

$$\varphi_2 = \arctan\left(\frac{2x_2}{x_0} \tan\left(\frac{\varphi_0}{2}\right)\right) \quad (4.8)$$

When the images have been matched, these equations can be used to calculate the range to an object.

4.2.3 Field of View

The field of view is an important characteristic to calculate distances and must be measured for the camera. Field of view was measured by placing a ruler at a distance in front of the camera and measuring the total distance seen across the image. Basic trigonometry then found the field of view. This was done multiple times to confirm the measurement. Results can be seen in table 4.1. The field of view used is the average of the data set and was found to be $\varphi_0 = 0.6249^\circ$.

Figure to show this?

4.2.4 Testing

MATLAB was used to test the range finding. The MATLAB script can be found Appendix H. It is unable to automatically detect and object so the user must

Table 4.1: Table of results to calculate the field of view of the camera

L (mm)	D (mm)	$\varphi(^{\circ})$
70	104	0.6435
90	135	0.6015
178	285	0.6054
214	345	0.6493
Average		0.6249

Table 4.2: Results of range finding test

Actual Distance (mm)	Pixel Difference in Images (pixel)	Calculated Distance (mm)	Error (%)
100	290	72	28
200	152	137	32

800	57	365	54
900	53	393	56
1000	51	408	59

select the template when prompted.

A stereo pair of images at different ranges were captured using the completed robot. To calculate the distance, a template from the right image of the ducks head was cross correlated with the left image. The maximum peak in the result was found and used as the match point. The distance was then calculated using equation (4.4), with $B = 42\text{mm}$, $\varphi_0 = 0.6249$ and $x_0 = 320$. Example images can be seen in figure 4.3 and an example NCC result can be seen in figure 4.4.

Table 4.2 shows the distances tested with the distance calculated using the above method. The ranges calculated were inaccurate. This could be down to the resolution of the camera being low, so one pixel change can potentially be a large distance error. Matching can only be done to the accuracy of a few pixels without extra effort and therefore can introduce a small error and cause a large distance error in the calculation.

Figure 4.3: Stereo pair of images of a rubber duck on a reel of solder

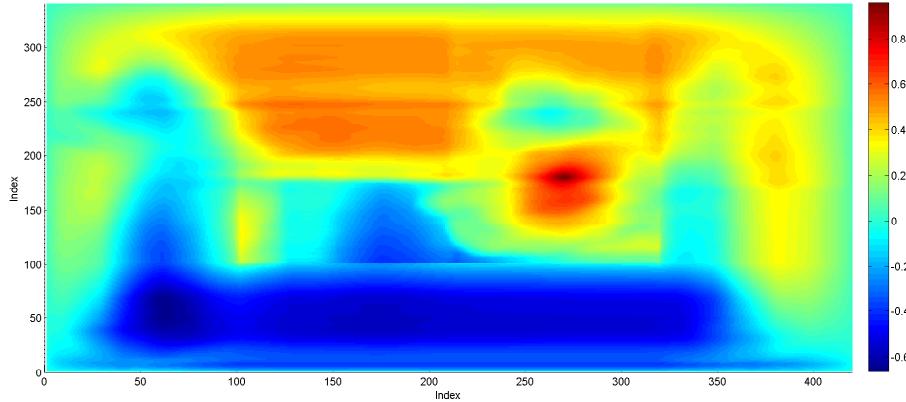

Figure 4.4: NCC results from matching using the duck's head from the right image as the template to the left image

4.2.5 Conclusions

Extensive testing of the effect of separation of the cameras has been done before ([Mrovlje and Vrancić, 2008](#)). Figure 4.5 shows that by increasing B will give you a larger range of detectable distances, but with a larger potential error with a low resolution camera. A separation of more than 100 pixels will result in around the same calculated distance due to the function being of the form $D = \frac{k}{x}$. This gives a range of distances that the can be detected. For $B = 42mm$, it is around $200mm$ to $1m$. An external frame could be made to mount the cameras with a greater separation distance to alter this characteristic on the robot.

The robot was designed to be small, and the cameras were chosen as a cheap alternative to more expensive products on the market. The test results show that using the cameras with a small separation and low resolution, the system is unable

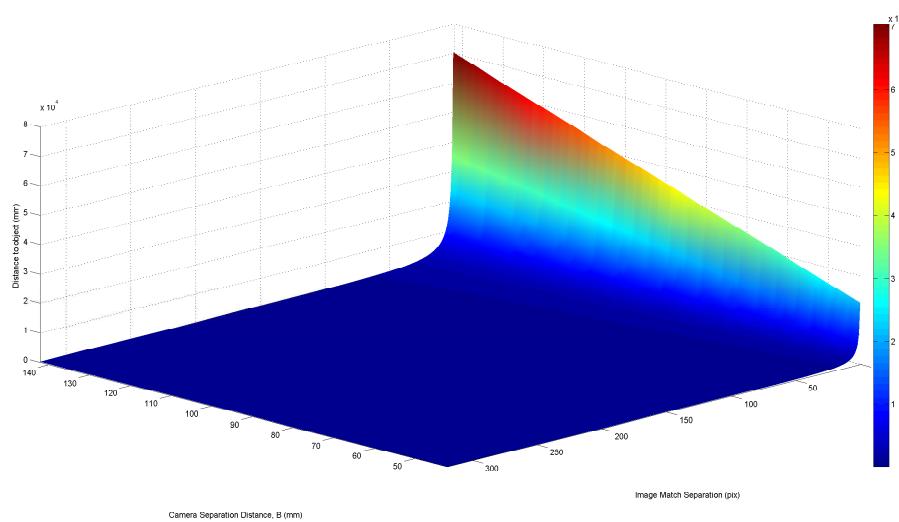

Figure 4.5: 3D Surface plot graph showing range of distances that can be calculated over a range of camera separation, B , values.

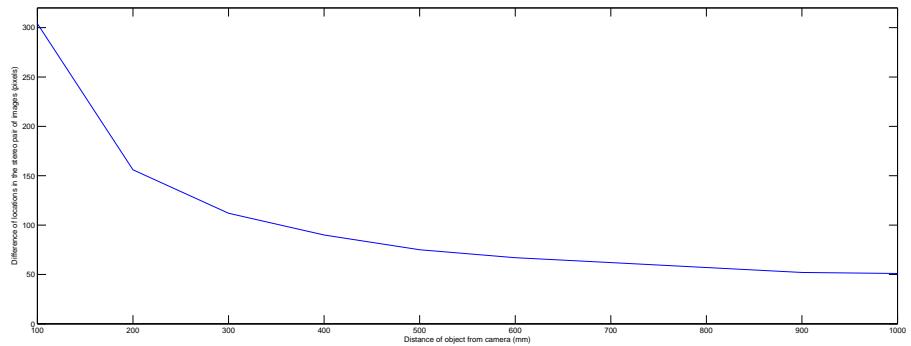

Figure 4.6: Graph showing Distance of the object against the difference in the match locations.

to accurately measure distances to objects seen. The separation of objects in the images is a reciprocal function and the data gathered in the test matches this characteristic, see figure 4.6. This means the system can perceive depth from the separation of the objects, but not accurately calculate the distance.

4.3 Fourier Transform

4.3.1 Background Research and the FFT

The Fourier transform is a common tool in signal processing. It transforms a time based signal to the frequency domain showing the frequency components contained

in the signal as a complex number. This is often displayed as magnitude and phase. The Fourier Transform is defined in equation (4.9) and two examples of signals and their Fourier Transforms are shown in figures 4.7 and 4.8.

$$X(f) = \int_{-\infty}^{\infty} x(t)e^{-j2\pi ft} dt \quad (4.9)$$

The Fourier transform is used in many areas of signal processing. It is used for filter design, system analysis and image processing as well as many others. It shows the frequency components of a time domain signal.

The equation for the Fourier transform in equation (4.9) is for continuous time. A discrete Fourier transform (DFT) exists for finite, equally spaced samples. This is commonly used in digital systems and is defined in equation (4.10). There exists a Fast Fourier Transform (FFT) which gives exactly the same results as the DFT, but is optimised in terms of number of multiplications done. The FFT will be used in implementation due to availability of code and speed of use.

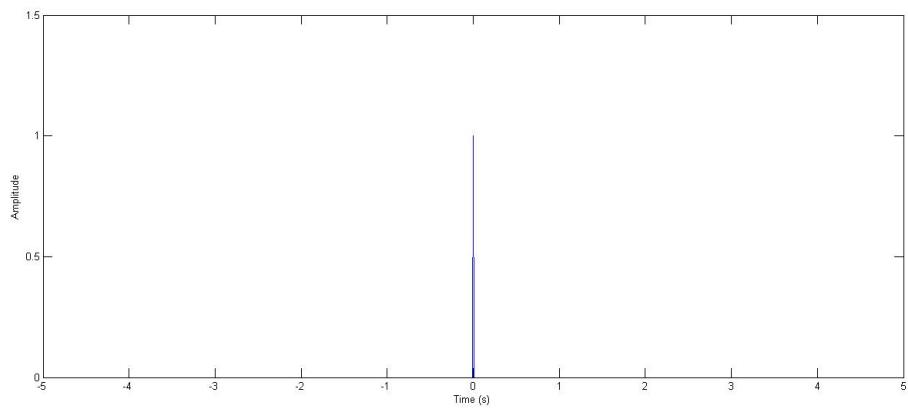

$$X[k] = \sum_0^{N-1} x[n]e^{-j\Omega_0 kn} \quad (4.10)$$

Where Ω_0 is the sample frequency

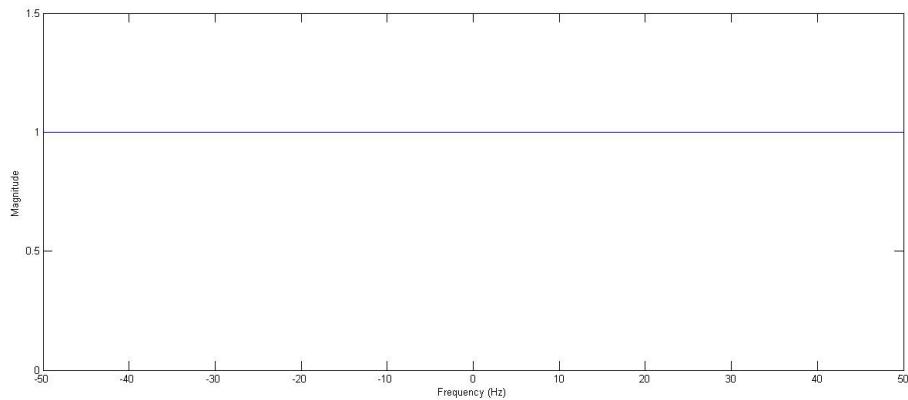

A property of the Fourier Transform of interest is the convolution theorem which states that convolution in time is multiplication in frequency and is defined mathematically in equation (4.11). As discussed in section 4.1.3, cross correlation is very similar to convolution. Cross correlation is defined in equation (4.12). With images, $f(t)$ is a real signal, its conjugate is exactly the same, $f(t) \equiv f^*(t)$ given that $f(t) \in \Re$. This means that to compute a cross correlation, the Fourier transform of the image and the template can be used and multiplied together. FFTs are quick and widely available so this should make the implementation more simple and fast.

$$\int_{-\infty}^{\infty} f(\tau)g(t - \tau)d\tau = f(t) * g(t) = X(f) \cdot Y(f) \quad (4.11)$$

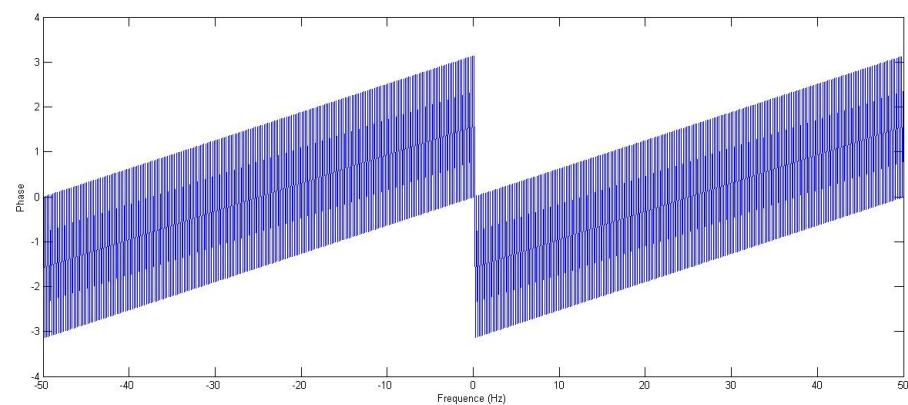

$$\int_{-\infty}^{\infty} f^*(\tau)g(t + \tau)d\tau = f(t) \star g(t) = X(f) \cdot Y(f) \quad (4.12)$$

$$f(t) \star g(t) = f(t) * g(-t) = F(f) \cdot G(-f) \quad (4.13)$$

4.3.2 Two Dimensional Fast Fourier Transform

A two dimensional Fourier transform exists for analysing two dimensional signals, namely in this application, an image. The Fourier Transform is shown in equation (4.14) and the discrete version is shown in (4.15)

$$F(u, v) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x, y) e^{-2\pi j(xu+yv)} dx dy \quad (4.14)$$

$$F(u, v) = \frac{1}{N} \sum_{x=0}^{N-1} \sum_{y=0}^{N-1} f(x, y) e^{-\frac{2\pi j(xu+yv)}{N}} \quad x, y, u, v \in \{0 \dots N-1\} \quad (4.15)$$

Figures 4.9 and 4.10 show the two dimensional equivalent test signals of figures 4.7(a) and 4.8(a) and the phase and magnitudes of their Fourier Transforms. There is a direct similarity between the 1D and 2D spectra; the magnitudes of the Dirac (figures 4.7(b) and 4.9(b)) are both constant values and the rectangular pulses both have a modulus sinc function magnitude (figures 4.8(a) and 4.10(a)).

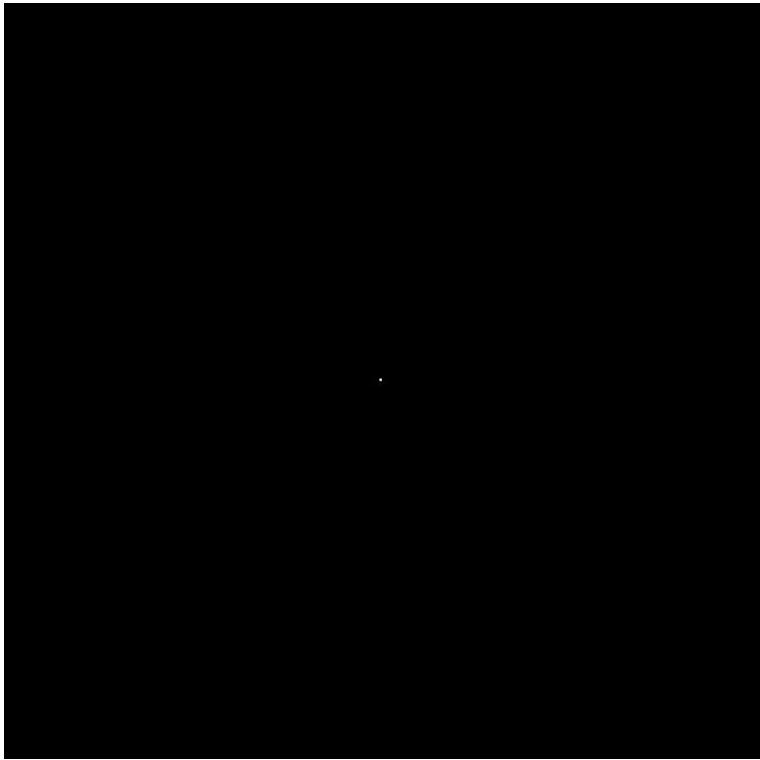

The 2D Fourier transform can also be optimised to a fast Fourier transform algorithm in a similar way as the 1D case. The algorithm, sometimes referred to as the Butterfly transform, is briefly discussed in Nixon and Aguado (2012) where it is explained that the algorithm can be easily applied to images with equal dimensions that are a power of 2. The algorithm utilises the separability property of the Fourier transform.

The 2D FFT can be implemented using a 1D FFT as follows:

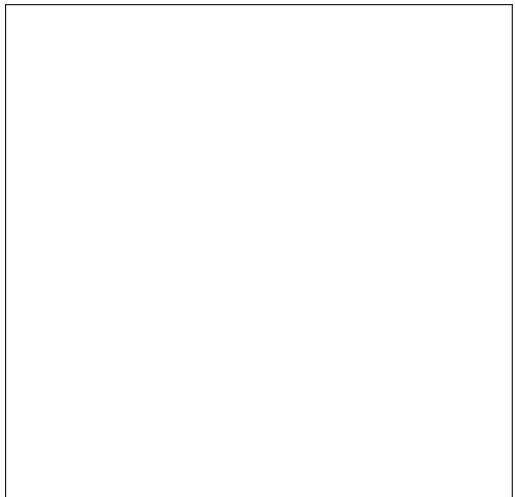

1. Calculate the 1D FFT of each of the rows of the 2D data. (An FFT of data of length n returns an array, also of length n)
2. Calculate the 1D FFT of each of the columns of the 2D data returned from the previous step.

Total number of FFTs done is $2n$ where n is the height/width of the image.

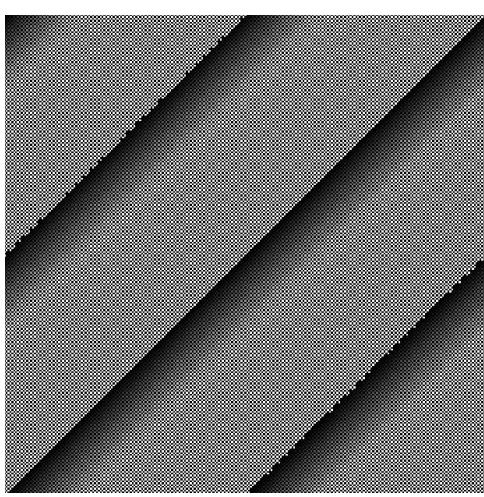

Maybe make a figure to help explain?

4.3.3 Implementing the FFT

The Atmel Software Framework ([Atmel Corporation, 2009](#)) included a digital signal processing library. This contained functions to compute the FFT of a real or complex array, the inverse FFT, magnitude and phase of complex data. Further restrictions are imposed by the DSP library used as the data must be an even power of 2, and that the data is in fixed point notation. This gives a usable dimension of 256×256 for processing images on the AVR. Though the height of an image from the OV7670 camera is 240 pixels, the image can be transformed so that it repeats for 16 rows at the bottom as the Fourier transform works on an assumption of the data being periodic.

The function *FFT2DCOMPLEX* in Appendix [H.1.1.5](#) is the realisation of a two dimensional fast Fourier transform on the microcontroller. The FFT function requires the data to be 4 byte aligned (A_ALIGNED) and of type *dsp16_complex_t*. The data must be given in fixed point notation and it is returned in fixed point notation. A 16 bit representation was chosen over 32 bit due to being more functions for 16 bit data available.

4.3.4 Testing of the FFT on AVR

4.3.4.1 1D FFT Test

A Dirac function and a rectangular pulse were used as test signals.

Figure [4.11](#) shows the input signal given to the AVR. It is a 256 long array of a Dirac function. This was then converted to the internally defined fixed point notation and passed through the Fourier transform method. The resulting complex array was then saved to a Comma Separated Value file and read into MATLAB. Figure [4.12](#) shows the calculated phase and magnitude plots of the output complex array. The magnitude is relatively flat and around the value of 1. In comparison with figure [4.7\(b\)](#), they are relatively similar. The phase, however, seems to be very different. Figure [4.7\(c\)](#) shows what was expected, but the two phase results seem not to match. This could be due to MATLAB having more accurate algorithms and a more accurate representation than the 16 bit fixed point used on the AVR. However, using a function in the DSP library to calculate the magnitude, the spectrum in figure [4.13](#) is obtained. This, though not exactly 1 as expected, is completely flat. It is computed from the same transformed data. It suggests that

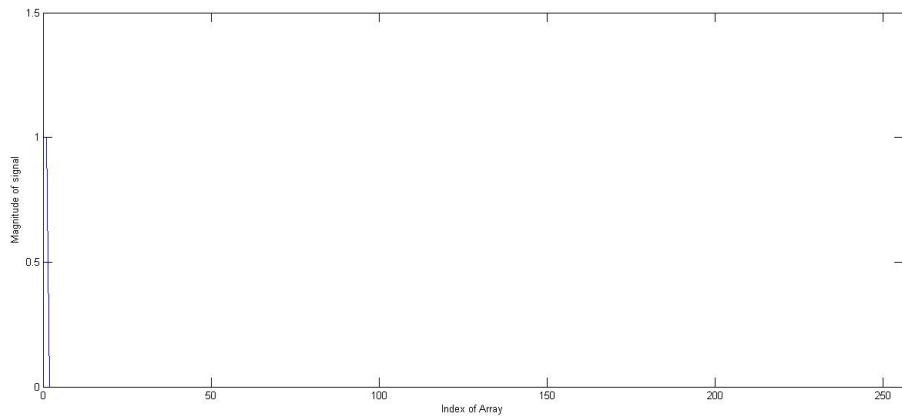

Figure 4.11: Input Dirac Signal for AVR fast Fourier transform

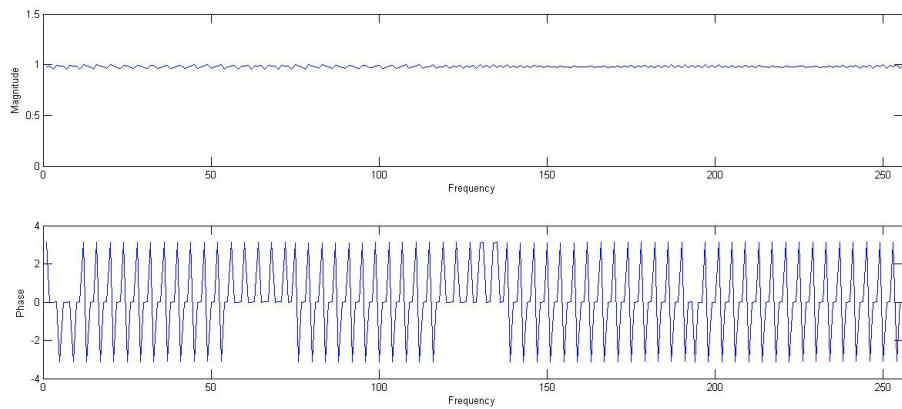

Figure 4.12: Output phase and magnitude of the complex output from AVR fast Fourier transform of a Dirac function

there is some internal compensation in the algorithms. The actual value in figure 4.13 is 0.9897 to 4 decimal places giving an overall error of 1.03%.

Figures 4.14, 4.15 and 4.16 show the similar outputs from the AVR when transforming the rectangular pulse. The result was renormalised from fixed point notation and the data was shifted so that the centre of the plot is frequency 0. Again, it can be seen the magnitude calculated from the complex output (figure 4.15) is different to the result when the magnitude is calculated on the AVR (figure 4.16). There are also differences in the result from the AVR and the result from MATLAB in figure 4.8, which can, again, be put down to the algorithms.

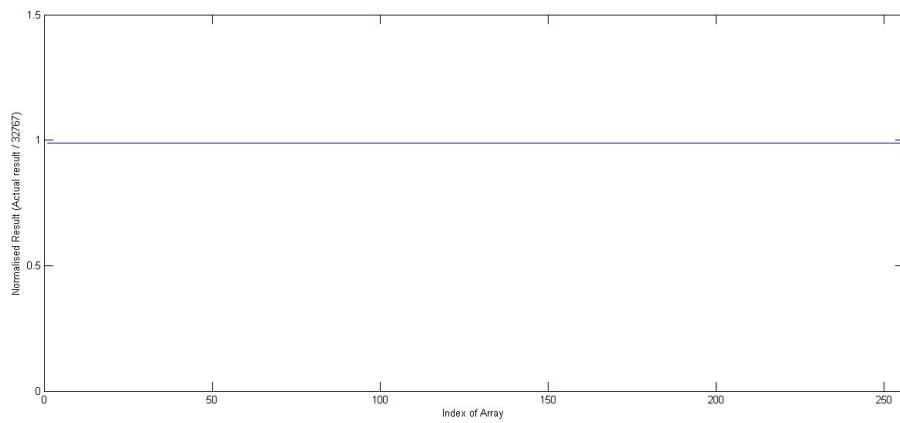

Figure 4.13: Magnitude calculated by the AVR of the Fourier transform of a Dirac function

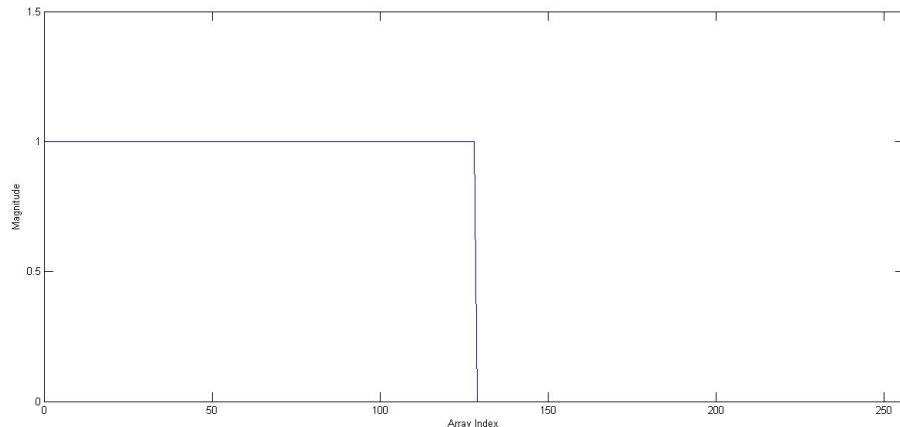

Figure 4.14: Input Rectangular Pulse for AVR fast Fourier transform

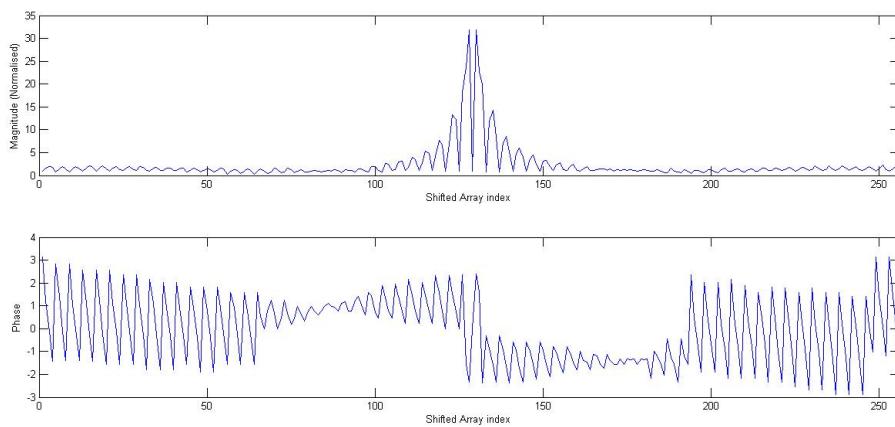

Figure 4.15: Output phase and magnitude of the complex output from AVR fast Fourier transform of a Rectangular Pulse

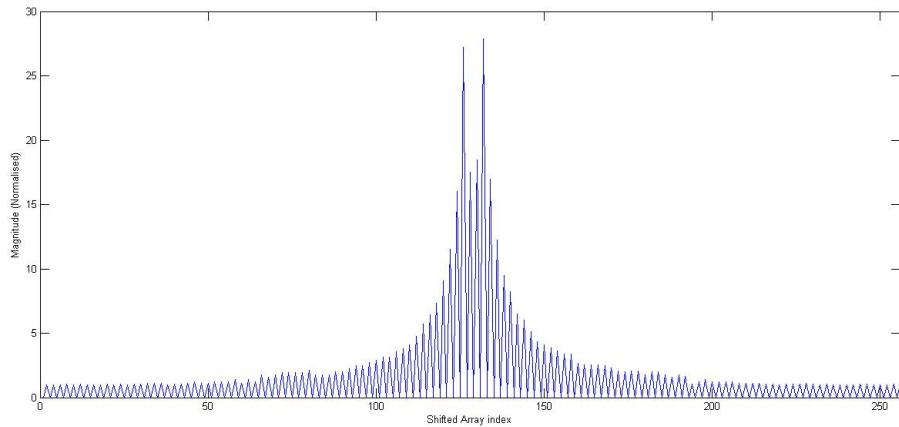

Figure 4.16: Magnitude calculated by the AVR of the Fourier transform of a Rectangular Pulse

4.3.4.2 2D FFT Test

Two test signals were used to test the 2D FFT on the AVR, a Dirac signal and a square wave, seen in figures 4.9(a) and 4.10(a). The internal method on the AVR was not able to compute the magnitude due to the method scaling all the values down causing truncation errors. The complex Fourier transform was obtained, saved to the SD card in CSV format and viewed in MATLAB. All data was normalised to omit the effects of scaling and the data shifted so that frequency 0 is in the centre. These test were done with a 64×64 2D data as with a 256×256 array, the AVR runs out of internal RAM to calculate the transform.

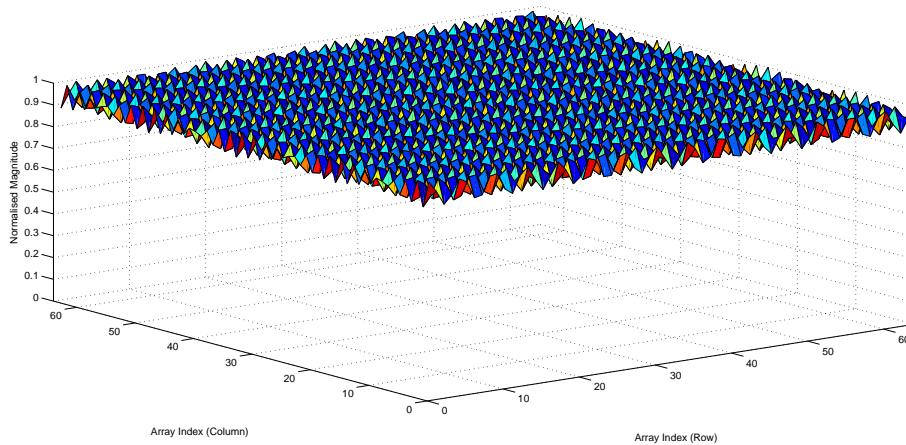

I would like to get this to work by the end but not vital.

The result of the Dirac test is seen in figure 4.17. A similar error is found in the magnitude, but the spectrum is generally flat with a small amount of ripple as seen with the 1D FFT in figure 4.13. The phase has similar issues as with the 1D FFT. However, there appears to be the correct pattern with the 2D phase, but rotated about 45° . This is also the case with the square wave test. The magnitude in figure 4.18(a) is very similar, with a distinct peak in the centre (frequency 0) and a sinc function extending vertically and horizontally from this. Again, however, the phase (figure 4.18(b)) seems to differ a lot from the expected result in figure 4.10(c).

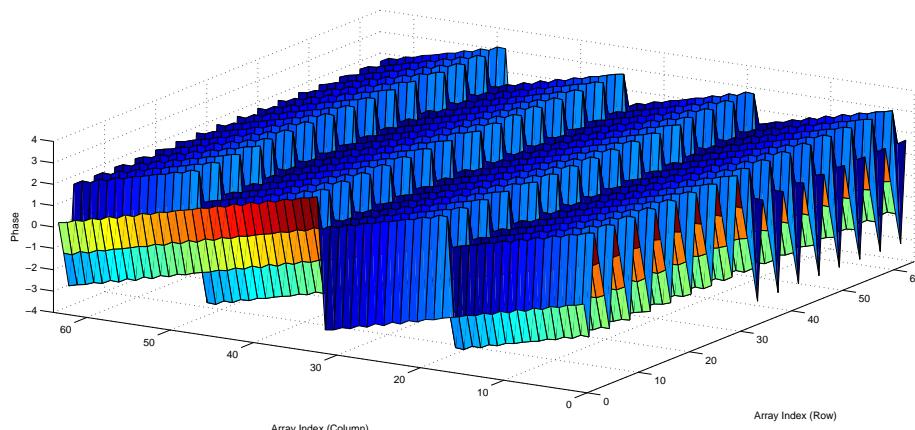

The transforms are calculated in real time with a 16MHz clock source. Table 4.3 shows the number of clock cycles taken to calculate the relevant sized transform. A 64×64 transform takes 39ms to compute with a 16MHz clock. This could

Table 4.3: Number of clock cycles taken to calculate the Transform of 64 or 256 long data set

Size of FFT Data		
	64	256
1D	5019	23599
2D	618168	-

(a) A 3D Plot of the normalised magnitude of the complex data returned by the 2D fast Fourier Transform on the AVR

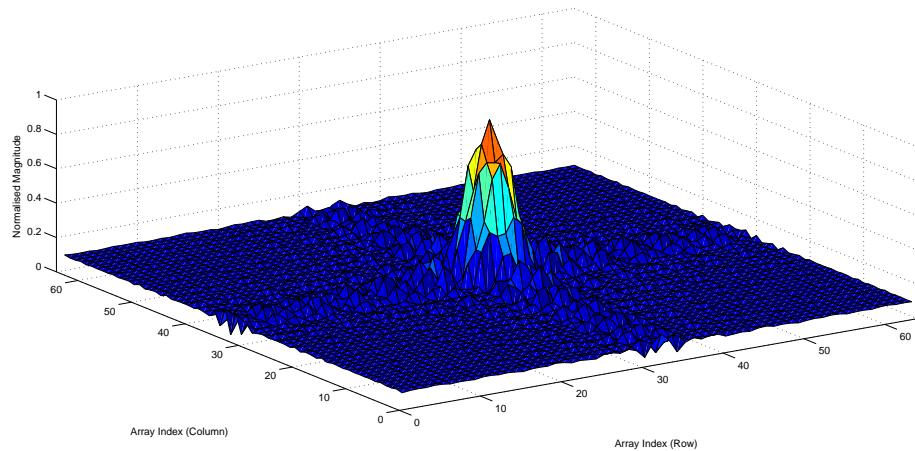

(b) A 3D Plot of the phase of the complex data returned by the 2D fast Fourier Transform on the AVR

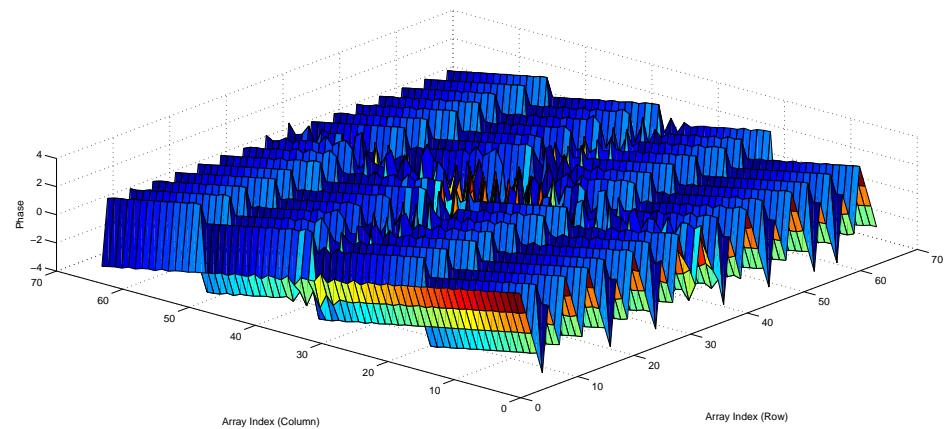

Figure 4.17: 3D Plots of the phase and magnitude of the Complex Data returned from the 2D FFT on the AVR of a 2D Dirac Function

be reduced by increasing the internal clock speed by using the PLLs available on the AVR, potentially taking it up to 33MHz and therefore halving the time to compute. A 64×64 image, however, is not practical for the application and

Maybe IFFT it too to find total errors in algorithm?

Chapter 5

Conclusions and Further Work

This work has led to a tested device which is mobile and has the capability to perform stereoscopic image processing. The system has the following parts:

1. Motor driving
2. Stereoscopic Cameras
3. SD Card memory
4. SRAM
5. Image Processing

The motor system is a simple, cheap method to move distances with reasonable accuracy. A better controller would allow variable speed and speed matching between motors. The system was shown to work to 4.5% accuracy over a 300mm distance.

A full image can be read from a camera and stored on an SD card in a FAT32 file system. This gives the ability of removable memory that can be viewed on a computer to see any internal logs. Images are stored in QVGA format (320 by 240 pixels) as a bitmap image.

An additional 4MB of SRAM memory is available to use on the robot allowing for large data arrays of the images to be kept in fast access RAM. The RAM is direct memory accessed so operation is almost seamless from internal memory.

Multiple comparison algorithms have been investigated and compared using the same test images. It was clear that, although at a necessity of more computations, the normalised cross correlation is the best with regard to overall reliability.

The Fourier transform was also investigated and implemented. The system allows for a 2×2 array of a square image with dimensions of 2^{2n} where $n \in \mathbb{N}$ and is limited by RAM space and time. The transform is speed optimised and in tests proved to be fairly accurate.

Range finding equations were then researched and derived, which use the characteristics of the camera and the separation distance between them to calculate distance to objects in view. The range finding capability was tested using MATLAB and it found that the system could not accurately calculate distances to objects. However, depth perception is possible even with low resolution cameras and small separation between them.

All aspects implemented on the robot have been shown to be functional. A faster processor would have been a good idea to use for image processing, but this could have developed other problems with the PCB. The Raspberry Pi or Steve Gunn's '*L'Imperatrice*', which both run a Linux operating system, would have been a good choice to remove the need for as much hardware design and existing image processing libraries could have been utilised to gain more functionality in the time.

Though the robots original application wasn't achieved, the end device is a base for a stereoscopic application. The system is a tested platform for future applications to be implemented on and additions can be made using the spare pins and bus connections on the PCB headers.

The system could be used in future projects to develop more functionality. Wireless communications could be added to the system to allow a connection to the computer and search algorithms can be implemented alongside distance calculations to make the robot aware of its surroundings.

5.1 System Operation

The system uses a debug USART available on J7 (57600bps, 8 data, 0 parity and 1 stop bit).

The system has two modes of operation, 'Auto Run' and Debug. By default, the Auto Run mode will run. Debug mode can be entered by the relevant command

Table 5.1: Table showing the Auto Run Commands Implemented

Command	Argument	Operation
B	int	Move backward by the argument value (millimetres)
F	int	Move forward by the argument value (millimetres)
J	int	Jumps to the command specified (0 indexed)
P	N/A	Takes a stereo pair of photos
q	N/A	Quits Auto Run and enters debug mode
R	int	Rotates by argument (degrees)

in the Auto Run procedure (see table 5.1) or by connecting Pin D23, available at Pin 1 of J9, to ground on system boot. The state of the robot is shown by the LEDs. Table 5.3 shows the meaning of the LEDs.

Auto Run mode runs a set of commands located in “*AutoRun.txt*” on the SD Card. If this file is not present, the system will run a default procedure defined in the code. A list of commands that can be run from this mode can be seen in table 5.1. The commands are specified by line If an invalid command is found, the system will exit and run the *System_Error* loop. The *System_Error* loop prints the status of all devices out once a second. By attaching a USART terminal, the error can be found.

Debug mode is a DOS-shell style terminal allowing the user to access methods and variables. This was used for development and debugging. A full list of commands can be seen in table 5.2.

Table 5.2: Table showing the available Debug Commands

Command	Argument	Operation
?		Shows the help prompt
A		Runs the Auto Run procedure in debug mode
B		Reads a Bitmap file and prints information
c		converts the working buffer from integer to fixed point
C		Converts the working buffer from fixed point to integer
d		Saves the Working Buffer to “Buffer_results.csv”
D		Frees the Memory pointed to by the Working Buffer
f		Reads “Buffer.csv” as a 2D Array of FFT_SIZE by FFT_SIZE
g		Saves the Complex Buffer to “Buffer_Complex.csv”
k		Prints the Complex Buffer
m		Computes the Magnitude of the 1D FFT of the Working Buffer
M F	(int)	Drive Robot forward by (int) millimetres (negative number for reverse)
M L		Dive Left Wheel Forward a full rotation
M q		Resets Motors
M R		Drive Right Wheel Forward a full rotation
M T	(int)	Rotate Robot by (int) degrees (positive turns Clockwise)
o		Displays the fixed point value for (int)1
P		Takes and stores Stereo Photos
r		displays the contents of the working buffer
R		Reads contents of “signal.bin”, representing 1D Signal. Integers, Big Endian
T		Reads contents of “signal2d.bin”, representing 2D Signal.
s		saves the working buffer
S		Saves the image in memory to a Bitmaps
v		Prints the status variables
1		computes the One Dimensional FFT of the working buffer. Returns magnitude.
2		Computes the Magnitude of the Two Dimensional FFT of the Working Buffer.
3		Computes the Complex 2D FFT of the working buffer and stores it in the Complex Buffer

Table 5.3: Table show the meaning of the LED lights. F - Flashing, X - Don't Care

MOTOR	LED					Meaning
	2	3	4	5	6	
Off	Off	Off	Off	Off	Off	System Initialising
On	X	X	X	X	X	Robot moving
Off	X	X	X	X	X	Robot not moving
X	On	On	On	X	X	System in Debug Mode
X	X	X	X	On	X	Left Wheel on a 'Tab'
X	X	X	X	Off	X	Left Wheel not on a 'Tab'
X	X	X	X	X	On	Right Wheel on a 'Tab'
X	X	X	X	X	Off	Right Wheel not on a 'Tab'
Off	On	Off	Off	X	X	Auto Run Mode - Robot taking photos
On	Off	On	Off	X	X	Auto Run Mode - Robot rotating
On	Off	Off	On	X	X	Auto Run Mode - Robot moving
Off	F	Off	Off	X	X	System Error - Generic
Off	F	F	X	X	X	System Error - SD Card Error
Off	F	X	F	X	X	System Error - Camera Error

Appendix G

Range Finding Derivations

G.1 Object is between the Cameras

Derivation from [Mrovlje and Vrančić \(2008\)](#).

$$B = B_1 + B_2 = D \tan(\varphi_1) + D \tan(\varphi_2) \quad (\text{G.1})$$

$$D = \frac{B}{\tan(\varphi_1) + \tan(\varphi_2)} \quad (\text{G.2})$$

$$D \tan\left(\frac{\varphi_0}{2}\right) = \frac{x_0}{2} \quad (\text{G.3})$$

$$D \tan(\varphi_1) = x_1 \quad (\text{G.4})$$

Dividing (G.4) by (G.3)

$$\frac{\tan(\varphi_1)}{\tan\left(\frac{\varphi_0}{2}\right)} = \frac{2x_1}{x_0} \quad (\text{G.5})$$

$$\tan(\varphi_1) = \frac{2x_1 \tan\left(\frac{\varphi_0}{2}\right)}{x_0} \quad (\text{G.6})$$

This can also be shown for the right camera:

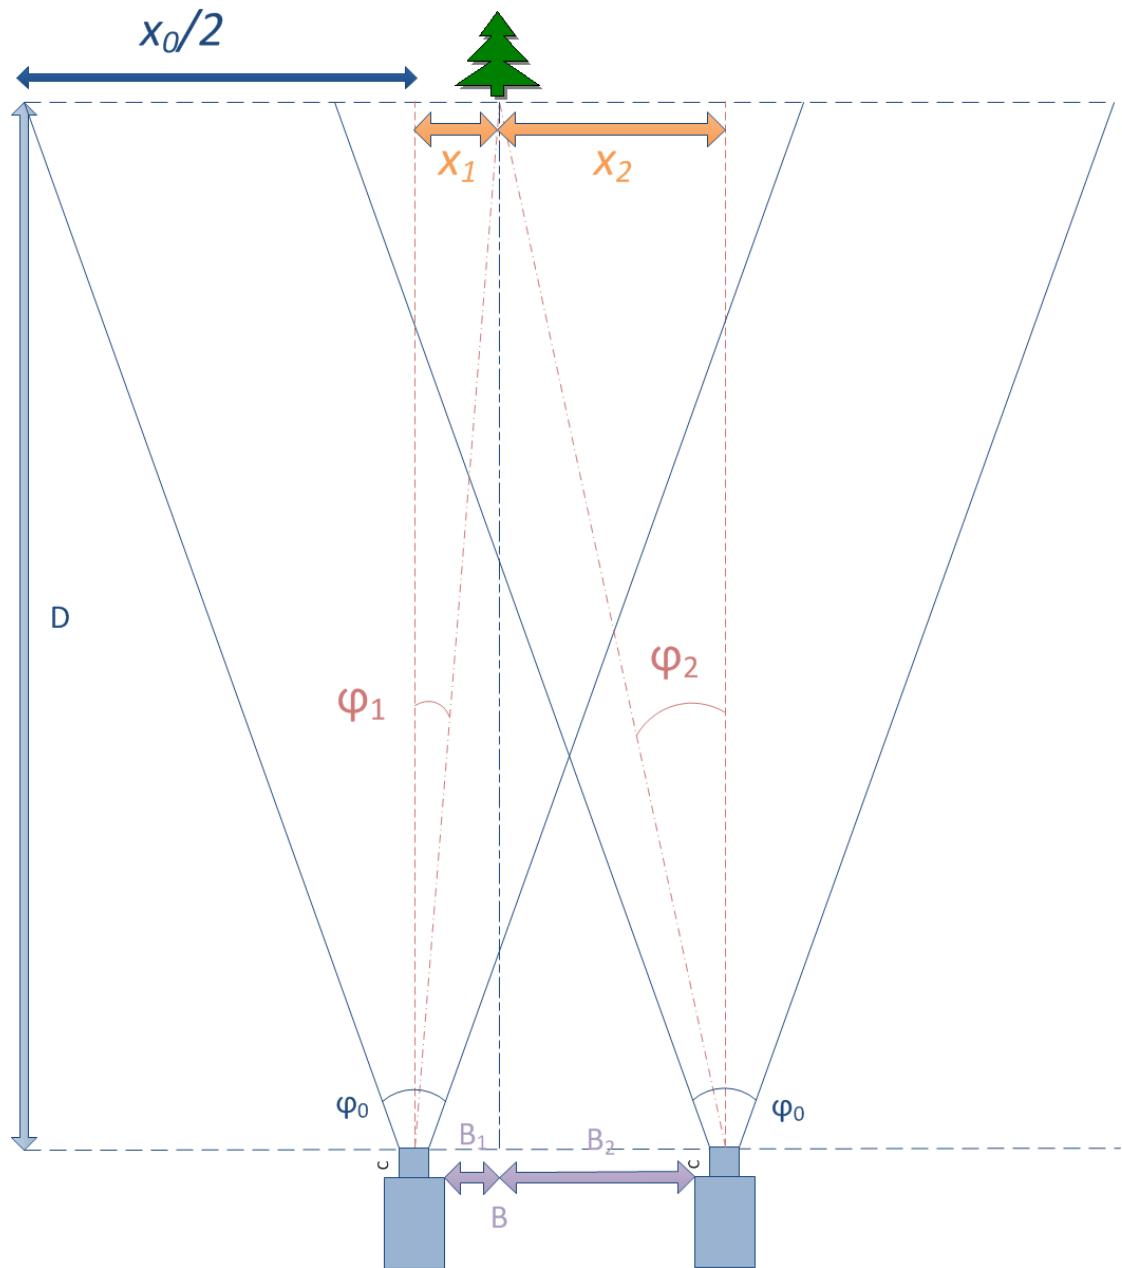

Figure G.1: Problem 1 - Object is between the Cameras

$$\tan(\varphi_2) = \frac{-2x_2 \tan(\frac{\varphi_0}{2})}{x_0} \quad (\text{G.7})$$

Substitution equations (G.6) and (G.7) into (G.2) gives

$$D = \frac{Bx_0}{2 \tan(\frac{\varphi_0}{2})(x_1 - x_2)} \quad (\text{G.8})$$

G.2 Object is to the same side in each camera

Derivation is based on the derivation from Tjandranegara (2005). Using figure G.2:

$$D \cdot \tan(\varphi_1) = x_1 \quad (\text{G.9})$$

$$D \cdot \tan\left(\frac{\varphi_0}{2}\right) = \frac{x_0}{2} \quad (\text{G.10})$$

$$\frac{\tan(\varphi_1)}{\tan\left(\frac{\varphi_0}{2}\right)} = \frac{2x_1}{x_0} \quad (\text{G.11})$$

$$\varphi_1 = \arctan\left(\frac{2x_1}{x_0} \tan\left(\frac{\varphi_0}{2}\right)\right) \quad (\text{G.12})$$

and similarly

$$\varphi_2 = \arctan\left(\frac{2x_2}{x_0} \tan\left(\frac{\varphi_0}{2}\right)\right) \quad (\text{G.13})$$

$$\theta = \varphi_2 - \varphi_1 \quad (\text{G.14})$$

Using the sine equality rule:

$$\frac{R}{\sin\left(\frac{\pi}{2} - \varphi_2\right)} = \frac{B}{\sin(\theta)} \quad (\text{G.15})$$

$$R = B \cdot \frac{\sin\left(\frac{\pi}{2} - \varphi_2\right)}{\sin(\theta)} = B \frac{\cos(\varphi_2)}{\sin(\theta)} \quad (\text{G.16})$$

$$D = \cos(\varphi_1) \cdot R \quad (\text{G.17})$$

Substituting (G.14) into (G.16), and then into (G.17):

$$D = B \cdot \frac{\cos(\varphi_2) \cdot \cos(\varphi_1)}{\sin(\varphi_2 - \varphi_1)} \quad (\text{G.18})$$

Where φ_1 is defined in equation (4.7) and φ_2 is defined in equation (4.8).

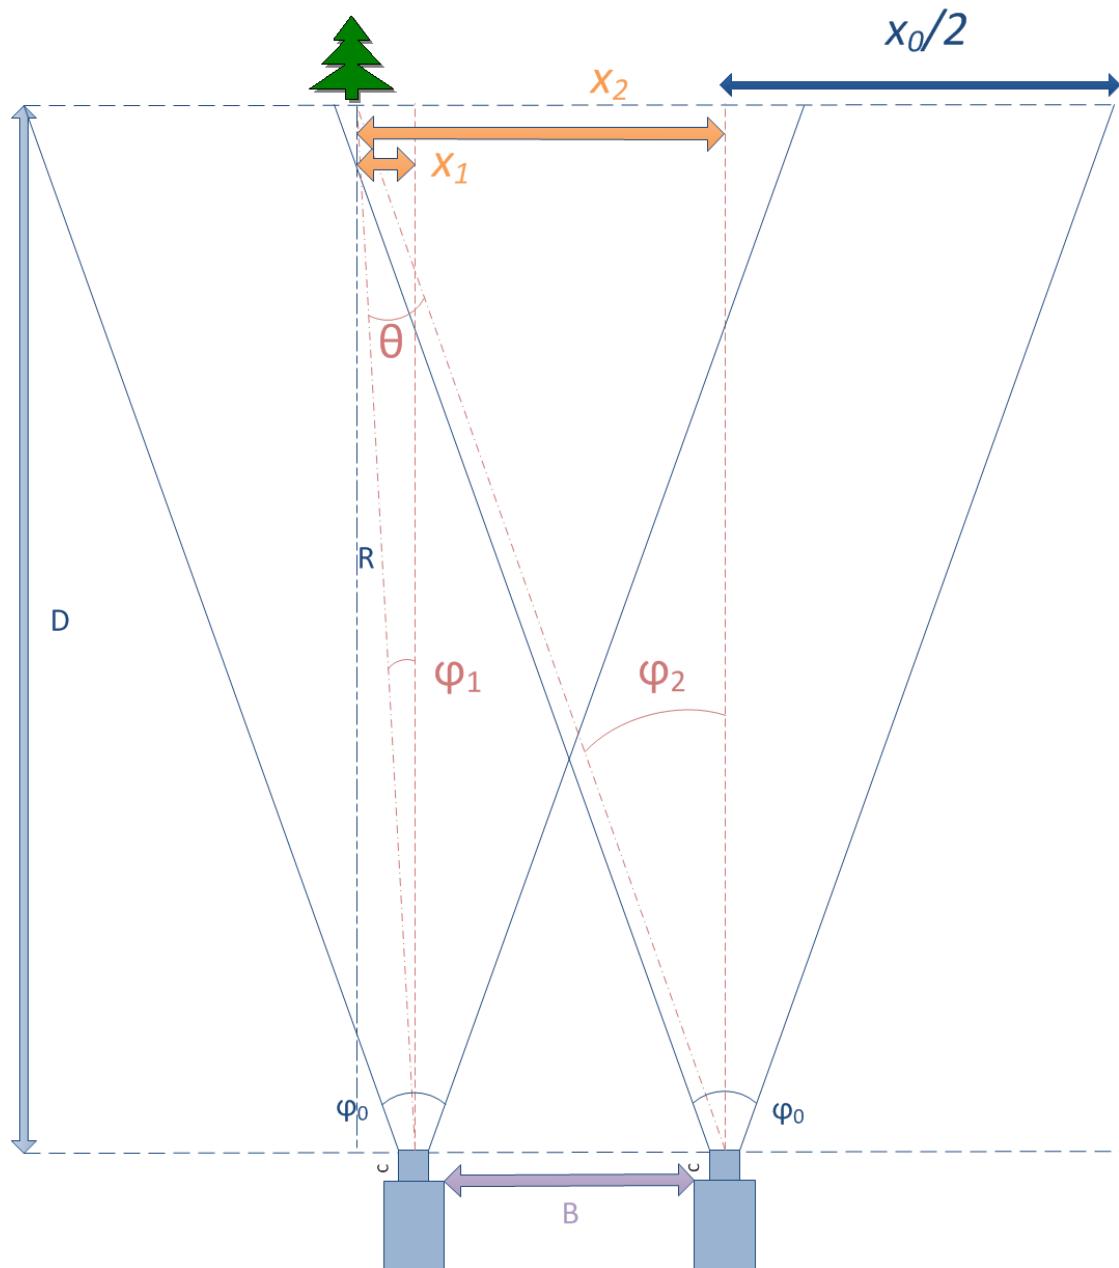

Figure G.2: Problem 2 - Object is to the same side in both cameras

G.3 Object is in front of a camera

The distance, D , in this problem is given by:

$$D = B \tan \left(\frac{\pi}{2} - \varphi_2 \right) \quad (\text{G.19})$$

Where φ_2 can be found from equation 4.8.

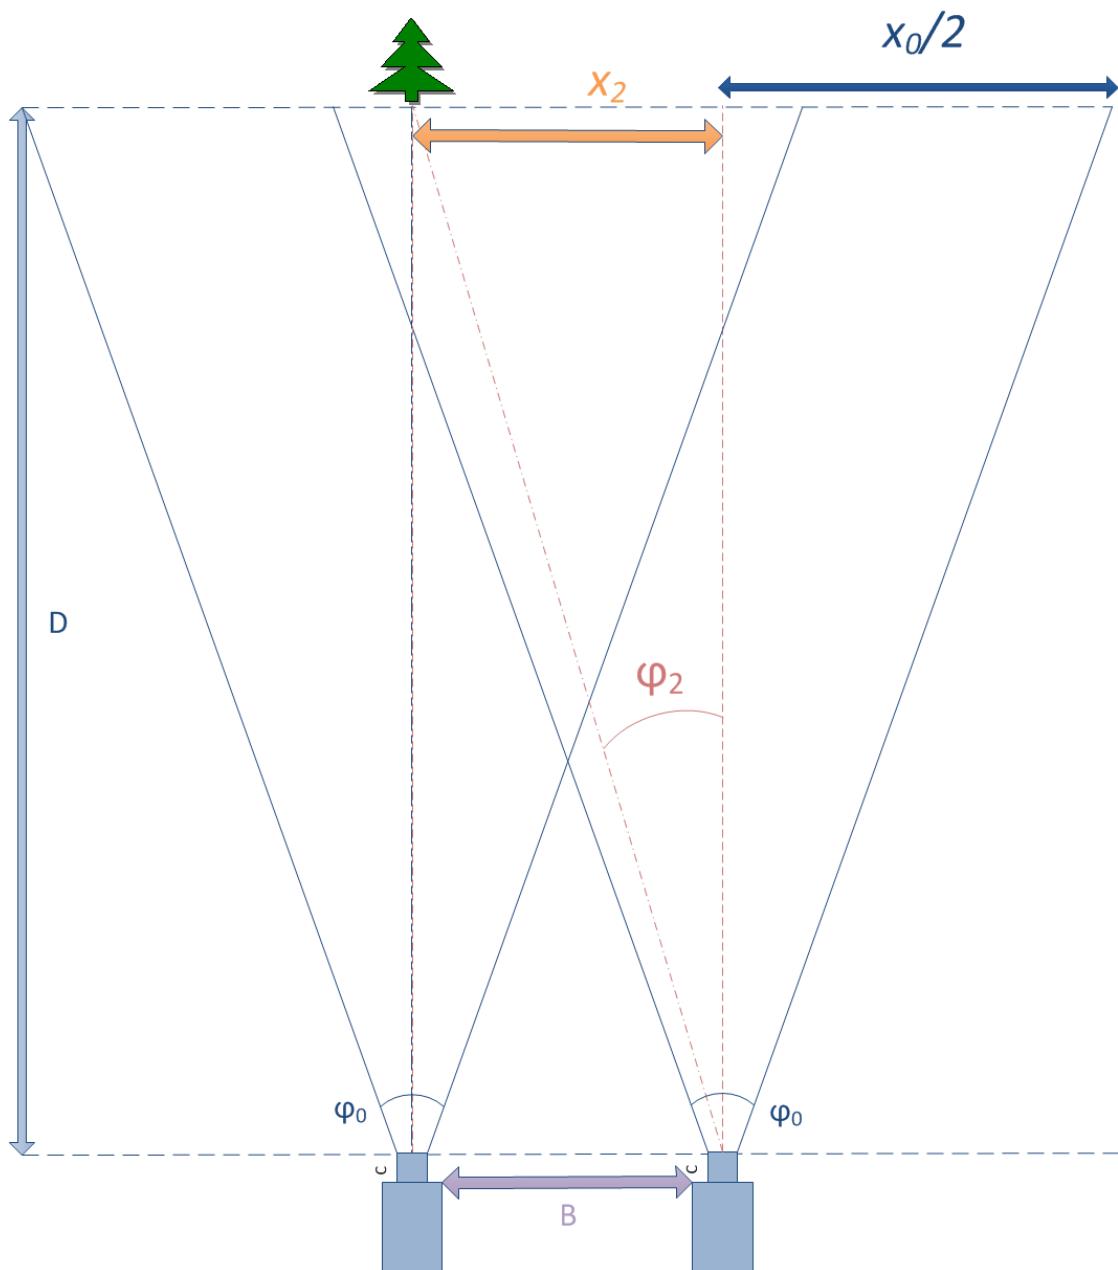

Figure G.3: Problem 3 - Object is directly in front of a camera
