A project report submitted for the award of MEng Electronic Engineering

TWO DIMENSIONAL STEREOSCOPIC MAPPING ROBOT

by Henry S. Lovett

This paper describes the research, design, build and testing of a stereoscopic mapping robot. Two cameras are used to locate objects and calculate distances to solid items. This allows an occupancy map to be built up of the unknown area. The object detection is done by a normalised cross correlation and uses derived equations to find distances. The camera used is an OV7670 by OmniVision delivering QVGA sized images. The end product will be a mobile wheeled robot that explores an unknown area. Multiple modules of the design have been developed and tested and all aspects will be brought together onto an AVR32 for the final product.

Chapter 1

Introduction

This report documents the designing, testing and building of a stereoscopic mapping robot. The end product will be a small, two wheeled robot with a roller ball, that will autonomously search and map an unknown area and produce an occupancy map of the searched area.

Stereoscopy in computer vision is the ability to calculate the locations and depths using images from two cameras that are used to triangulate and estimate distances ([Saxena et al. \(2007\)](#)). By using two cameras on the same plane, separated by a set horizontal distance, the depth of the observed scene can be perceived by the system.

An occupancy map is a representation of an area where a location is given a value of either *free*, *occupied* or *unknown* [Thrun \(2003\)](#). Three dimensional occupancy maps can also be generated, such as the OctoMap ([Wurm et al. \(2010\)](#)). Objects can also be tracked using an occupancy map and statistics ([Fleuret et al. \(2007\)](#)).

The purpose of a mapping robot is to build a representation of the area around it. This then facilitates the use of any application that requires prior knowledge of the area. One algorithm that is used to build up an occupancy map is the S.L.A.M. algorithm ([Thrun and Montemerlo \(2006\)](#)) and is used in other mapping robots([Se et al. \(2002\)](#)). Accurate mapping robots tend to use laser range finders ([Ruhnke et al. \(2011\)](#)).

Stereovision is a small section of computer vision which is widely used in many applications, including Microsofts Xbox Kinect ([Microsoft \(2012\)](#)), where stereo vision is used to locate a game player in order to use their movements to control

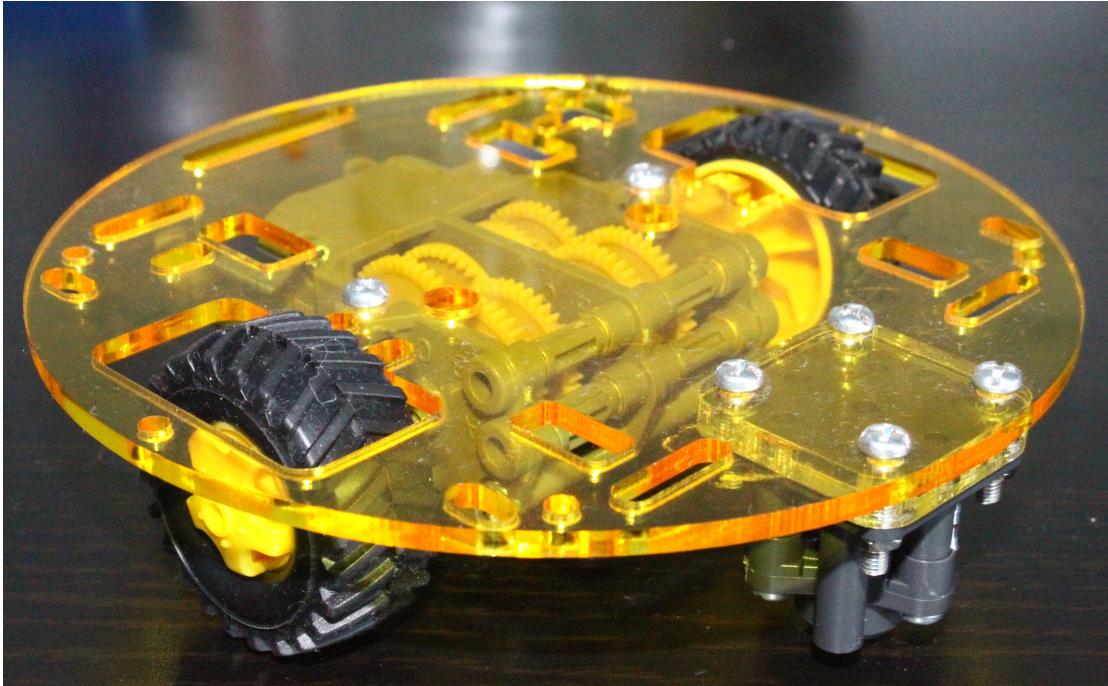

Figure 1.1: The base of the robot will use

the game. [Mrovlje and Vrančić \(2008\)](#) uses stereovision to be able to locate the distance to a marker.

The stereovision mapping robot discussed in this report is a low cost alternative to other robots which use laser range finders or high quality cameras ([Se et al. \(2002\)](#)). The robot will use the base seen in figure 1.1 and use two OmniVision OV7670 cameras delivering up to VGA format images.

Chapter 2

Research

The research done for this project is split into three sections:

1. Hardware
2. Software, broken down into:
 - (a) Firmware
 - (b) Algorithms

Hardware and Firmware research will be discussed in this section. Vision algorithms are looked at in detail in chapter [4](#).

2.1 Hardware Research

2.1.1 Microcontrollers

The robot is to be designed with a budget of £80 (not including P.C.B.). The choice of microcontroller will be an important one, as a compromise between cost, power and usability must be made. There are two main brands of microcontrollers present in the consumer market: ARM and Atmel AVRs.

ARM is an architecture which is developed by ARM Holdings. ARM devices come in a many varieties: ARM9, ARM7, Strong ARM, ARM Cortex etc. Whilst ARM Holdings do not fabricate and sell the devices themselves, many companies, such as Texas Instruments, use the architecture and manufacture their own devices.

For this comparison, the Stellaris by Texas Instruments will be examined. ARM cores are based on a RISC Harvard architecture and tend to be 32-bit with a high clock speed. ARM microcontrollers have onboard support for SPI, I^2C , PWN, ADCs and have Flash, SRAM and EEPROM memory.

Atmel have a variety of products in the microcontroller market. They range from 8-bit, low clock speed devices for the hobbyist, the ATMega and ATTiny series to an improved 8-bit variant, XMega, and a 32-bit design, AT32UC3C. XMegas and AVR32s tend to have higher clock speeds than the ATMegas. The AVR core is also a Harvard RISC architecture, but mainly 8-bit. Atmel devices often have on board peripherals such as I^2C (called TWI on AVR), SPI, ADCs as well as a number of different memories: Flash, EEPROM and SRAM. An AT32UC3C0512C, ATXmega256A3BU and ATMega644P will be compared in this section.

Table 2.1 shows a brief summary of some common ARM and AVR microcontrollers. The Stellaris offers the most power with the largest DMIPS performance. However, due to the necessity of floating point operations, the AT32 clearly has a distinct advantage by having a built-in floating point unit. The XMega and ATMega do not offer enough power and are restricted by a small amount of SRAM and Flash. All devices looked at use 3.3V supply and have basic communication protocols (SPI, I^2C). Overall, the AT32UC3C0512C is the best choice with a high throughput, a floating point unit and a vast amount of GPIO and communications. There is no EEPROM which may be desirable, but these can be added onto and SPI or I^2C bus. This device, although slightly more costly, is best suited to this application out of the selection researched.

2.2 Firmware

2.2.1 Camera

The camera used is the OV7670 camera by OmniVision. Steve Gunn provided source code for use on the II Matto development board which uses an ATMega644P and also has an onboard SD Card reader. The original code streamed video from the camera to a colour TFT screen. It is supplied on a small breakout board with a FIFO buffer. The camera operation is discussed in section 3.1. Many implementations of firmware for this camera exist.

	ARM Stelllaris	AT32UC3C0512C	XmegaA3BU	ATmega644P
Clock Speed (MHz)	80	33 or 66	32	12
DMIPS	100	91	-	20 MIPS
Package	100 LQFP or 108 BGA	64, 100, 144TQFP	64 QFP or QFN	40 DIP, 44 TQFP, 44 QFN
Cost of 1 unit(£)	10.30	15.39	6.65	6.86

ADCs	16	16	16	8
Timers	4	3 16-bit	7 16-bit, 8 8-bit	2 8-bit, 1 16-bit

Table 2.1: Comparison Table of some common microcontrollers. Data of microcontroller taken from [Atmel Corporation \(2012a\)](#), [Atmel Corporation \(2012b\)](#), [Atmel Corporation \(2012d\)](#) and [Texas Instruments \(2012\)](#). Costings from [Farnell \(2012\)](#)

2.2.2 Atmel Software Framework

Atmel offer a software framework which contains basic code and device drivers for many of their Xmega and AT32 devices [Atmel Corporation \(2012c\)](#). There are also many AVR application notes which provide explanations and example code for protocols like TWI, SPI and timers. These application notes are aimed at older devices like the ATTiny and ATMega and are generally written for IAR Embedded Workbench compiler, as opposed to the AVRGCC compiler used within Atmel Studio.

Chapter 3

Initial Hardware and Firmware Development

For initial development, the *Il Matto* board, designed by Steve Gunn, which has an ATMega644P, was used. The system is clocked at 16MHz and has an on-board SD card connector.

The following section is broken down into the following parts:

1. Camera Code
2. SD Card
3. Circuit and PCB Development

3.1 Camera

The camera used is an OV7670 by OmniVision. It is mounted onto a break out board and connected to a AL422B FIFO Buffer. The breakout board has all passive components needed and a 24MHz clock mounted. The schematic for the device can be seen in Appendix 2.

Original code for the camera operation was given by Steve Gunn, of which I used to gain the operation required. The code streamed continuous video to a TFT screen. The operation required was to take a single photo.

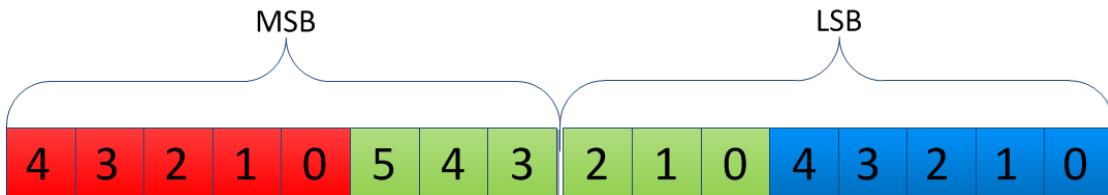

Figure 3.1: RGB565 pixel format

3.1.1 Single Camera Operation

The camera uses a SCCB Interface([OmniVision \(2007\)](#)) created by OmniVision. This is almost identical to the I^2C Interface by Phillips. The original code used a bit-banged SCCB interface which was very slow and used up processing time. This was changed to make use of the built in interrupt driven I^2C interface (named TWI in Atmel AVR's)¹. This communication bus is used to set up the control registers of the OV7670 to enable operation in the correct format. RGB565 is used in my application.

RGB565 is a 16 bit pixel representation where bits 0:4 represent the blue intensity, 5:10 is the green intensity and 11:15 represent the red intensity (see figure 3.1). This is a compact way of storing data but only allows 65536 colours. Greys can also appear to be slightly green due to an inconsistent colour ratio of the green field.

The camera must use a high speed clock in order to ensure the pixels obtained are from the same time. This makes it difficult for an AVR's (ATMegas typically clocked at 12-16MHz) to be able to respond to the camera quick enough. This highlights the importance of the necessity for a FIFO Buffer.

The OV7670 is set up so that the VSYNC pin goes low at the beginning of every full frame of data and HREF is high when the data being output is valid. The pixel data is then clocked out on every rising edge of PCLK. To control the buffer, WEN (write enable) is NAND with the HREF signal. When both are high, the write enable to the buffer will be active and the data will be clocked in by PCLK. In order to acquire a full frame, the first VSYNC pin is set up to interrupt the AVR to enable WEN. The operation is then automatic and all the data is clocked into the buffer until the second interrupt of VSYNC where WEN is disabled. At this point, the entire frame of data is stored in the buffer.

¹ I^2C , SCCB and TWI are all the same but are called differently due to Phillips owning the right to the name " I^2C "

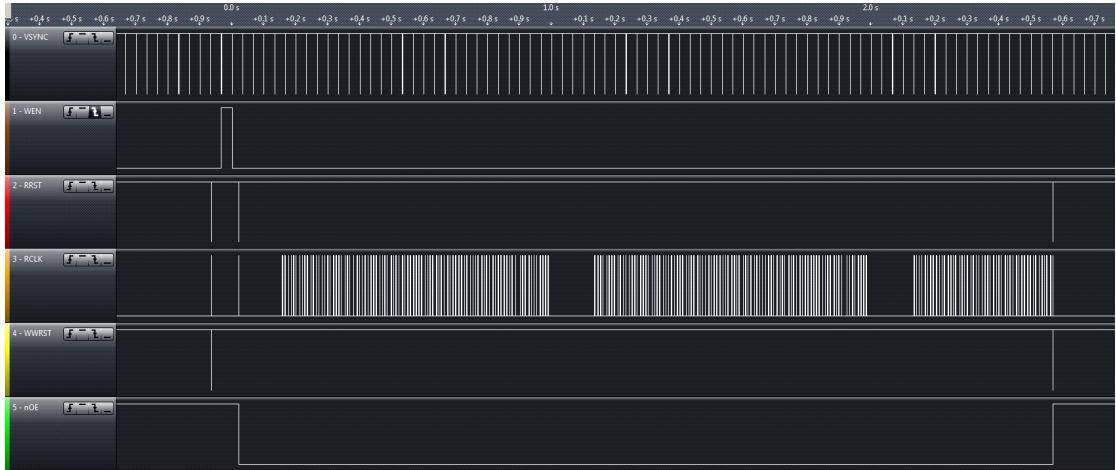

Figure 3.2: Signals generated to control the OV7670 capture and read

To obtain the data from the buffer, the AVR sets output enable and manually pulses the read clock. Valid data is available on the input port chosen. All the data is then read in half a pixel at a time. The entire operation can be seen in figure ???. Difficulties arose at this point with the storage of the data. The ATMega644P has 4kB of internal SRAM, but 153.6kB of memory is needed to store a single image at QVGA (320 by 240 pixels) quality.

Firstly, data was sent straight to a desktop computer via a COM Port using USART. A simple desktop program was written in C# to receive and store all the data, and to make a Bitmap image from the data. This method was slow, taking around 30 seconds to transmit one uncompressed image.

The second option was to use extra memory connected to the microcontroller. An SD card was decided is used as FAT file system. This allows data to be looked at by a user on a computer. Text log files are also written to aid debugging. This is discussed in section 3.2.

3.1.2 Dual Camera Operation

In order for stereovision to be successful, two cameras separated by a horizontal distance, B , will need to be driven at the same time to obtain photos within a small time frame of one another.

The buffers have an output enable pin so the data bus can be shared by both cameras to the AVR. All buffer function pins are driven from pins, although a demultiplexer could be used if pins are short. The ATMega644P offers three interrupt pins, two of which are used by the two VSYNC pins for the cameras.

Two ISRs are used to control the VSYNC method and when taking a photo, both frames are taken at a time period close together to capture the same scenario. The data for both images are read back from one and then the other by the AVR.

A major problem now occurred with using the I^2C interface to set up both cameras. The camera has a set I^2C address of 21_{16} , which cannot be changed. Multiple I^2C devices with exactly the same address cannot be used on the same bus. Two solutions to this are possible: driving one from I^2C and one from SCCB, or using an I^2C multiplexer. By using two different buses, there can be no bus contention. However, SCCB is slow and processor-hungry as it deals with the protocol bit by bit. Space for the code then has to be made and this code cannot be reused.

An I^2C multiplexer sits on the bus and has multiple output buses. The master can then address the multiplexer and select whether to pass the bus to bus 0, bus 1 or not allow the data to be transferred. This saves processor time, but means a write operation has to be done to select the camera bus before being able to write to the camera. This slows down the operation, but not as much as using SCCB. The main disadvantage to the I^2CMUX is the extra hardware needed; firstly the MUX itself, but also 7 extra resistors to pull up the two extra buses and the three interrupt lines must be added.

Overall, the disadvantages posed by using a MUX are small and simplify the operation and reduce the code size so an I^2CMUX will be used. A suitable multiplexer is the Phillips PCA9542A ([Phillips \(2009\)](#)).

Operation to read an image is identical to using one camera. An ID number is passed through the functions to make a decision on the pins to use to read the buffer and to enable the output. Care was taken to avoid bus contention, but no checking procedure is explicitly in place. Both images are then read back from the buffers and stored to memory.

3.2 SD Card

To use the SD card, the FATFS library ([Electronic Lives Manufacturing \(2012\)](#)) was used. The library supplies all the functions for writing a FAT File System in the files *ff.c*, *ff.h*, *ffconf.h*, *diskio.c*, *diskio.h* and *integer.h*. The *diskio.h* functions control what device is being used - SD/MMC Card, USB drive etc. The *ff.h* header contains all the functions to write to in a FAT File system.

	Bitmap	JPEG	PNG	GIF
Extension	*.bmp	*.jpg /*.jpeg	*.png	*.gif
Compression	No	Lossless and Lossy	Lossless ZIP	Lossy
File Size of 320 by 240 pixel Image (kB)	225	20	23	24
Bits per Pixel	8, 16, 24 or 32	24	24, 32 or 48	24, but only 256 Colours

Table 3.1: A table comparing different image formats available ([Fulton \(2010\)](#))

An SD card was chosen due to it's small size, low cost and a large data storage. The cards work using an SPI bus which can be used for other devices within the system so the card only uses one extra enable pin in hardware to function.

3.2.1 Storing Images

Many image formats are common, such as Joint Photographic Expert Group (JPEG), Portable Network Graphics (PNG), Bitmap (BMP) and Graphics Interchange Format (GIF). Table 3.1 shows a summary of some common image formats.

It is clear that the best choice for images would be either PNG or JPEG. However, these require much computational time to compress the image into the correct format. To avoid compression, and thereby save processing time, bitmap was chosen at the expense of using more memory. The data in a bitmap image is also stored in RGB format so can be read back easily when processing the data. Appendix 2 shows the make up of a Bitmap File that was used.

By writing the image in this format, the images are then able to be opened on any operating system. This aids debugging and allows the prototyping of image algorithms in a more powerful environment. Figure 3.2 shows a photo taken by the OV7670 and stored on a SD card.

3.2.2 User Interface

The ATMega 664P pinout for the dual camera operation can be seen in table 3.2. Due to a lack of available GPIO pins, an ATMega 168 was added on the I^2C bus to

Figure 3.3: An Example Image taken using the OV7670 and stored as a Bitmap on the SD Card

	Port A	Port B	Port C	Port D
0	Data 0	SD Write Protect	I^2C - SCL	No Connection

7	Data 7	SPI Clock	Output Enable 1	Write Reset 0

Table 3.2: Pin Connections of the ATMega644P for Dual Camera Operation.

act as a port extender. The ATMega168 accepts a read or write, places the written data on Port D and reads in the lower nibble of Port C. When a button is pressed, this is stored in the ATMega168 until a read has been done. This is so the master (644P) does not miss any button presses while busy doing lengthy operations such as writing an image. The code is based on [Atmel Corporation \(2007\)](#), written for IAR Compiler. This code was altered to compile with GCC under Atmel Studio. AVRs contain a hardware based I^2C protocol that is interrupt based in software. The interrupt service routine of the TWI vector is a state machine which loads the data to send, stores received data, responds to acknowledges and address calls and deals with bus errors that can occur.

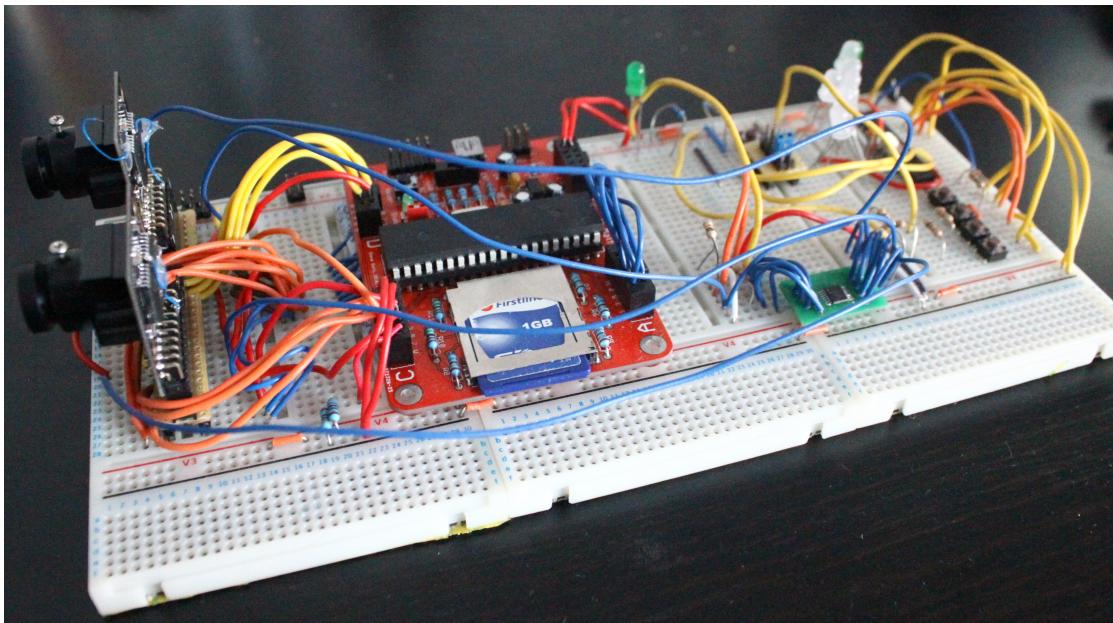

Figure 3.4: Prototype of Dual Camera operation.

3.3 Circuit and PCB Development

3.3.1 Il Matto Development

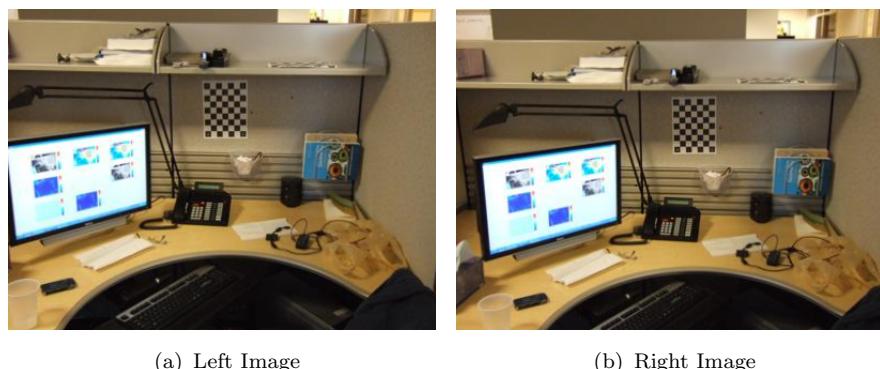

Figure 2 shows the circuit diagram for the prototype. This uses the Il Matto development board for the main microcontroller. The prototype can be seen in figure 3.3.

Chapter 4

Investigation into Vision Algorithms

4.1 Comparison

In computer vision, there are many different ways of comparing two similar images. These include the sum of absolute differences (S.A.D.) ([Hamzah et al. \(2010\)](#)), the sum of squared differences (S.S.D.) [Mrovlje and Vrančić \(2008\)](#) and normalised cross correlation (N.C.C.) [Zhao et al. \(2006\)](#). Each of these methods will be explained and tested to compare them. All testing will use images seen in figure 4.1. Each test uses the same size of image to compare to of 50×50 pixels of the same part of the image.

(a) Left Image

(b) Right Image

Figure 4.1: Stereoscopic Test Images from MATLAB Examples

4.1.1 Sum of Absolute Differences

Given two identically sized two dimensional matrices, A, B , of dimensions I, J , SAD is defined as

$$SAD = \sum_{i=0}^{I-1} \sum_{j=0}^{J-1} |A[i, j] - B[i, j]| \quad (4.1)$$

This method takes each sub image and subtracts the observed sub image from the expected. All differences are then added together. This algorithm is simple and requires a small amount of computation. The algorithm returns values where a small result means the two images are well matched.

4.1.2 Sum of Squared Differences

$$SSD = \sum_{i=0}^{I-1} \sum_{j=0}^{J-1} (A[i, j] - B[i, j])^2 \quad (4.2)$$

This is very similar to S.A.D. but adds more complexity by squaring each difference. This removes the ability of equally different but opposite differences cancelling each other out (grey to white of one pixel will cancel out a white to grey difference in the other with SAD). Again, a low result is a match in this case.

4.1.3 NCC

$$NCC = \frac{1}{n} \sum_{i,j} \frac{(A[i, j] - \bar{A})(B[i, j] - \bar{B})}{\sigma_A \cdot \sigma_B} \quad (4.3)$$

Where n is the number of pixels in A and B ,
 σ is the standard deviation of the image, and
 \bar{A} is the average pixel value.

NCC is very similar to cross correlation, but normalised to reduce the error if one image is brighter than the other. This is common in computer vision ([Tsai and Lin \(2003\)](#)) and cross correlation is often used in digital signal processing, so fast algorithms have been made to calculate this.

Unlike S.S.D. and S.A.D., the normalised cross correlation gives a high value for a match. The downside to this algorithm comes with the complexity of the equation,

containing division and the necessity to square root a number in order to calculate the standard deviation. These operations are rarely implemented in hardware and are time consuming to carry out. They also require floating point registers and operates slowly on a microcontroller with a small amount of floating point registers.

4.1.4 Comparison

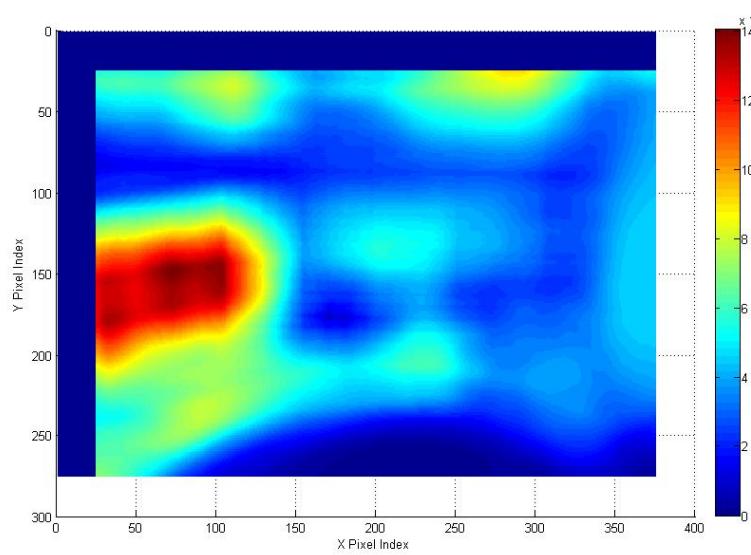

To compare these equations, a 50 by 50 image taken from the right picture was compared with the left image over the entire valid range. The coordinates on the graph give the centre pixel of the calculation.

Each of the graphs show the correct area being indentified as a match, but this also highlights the downfalls of the SAD and SSD. The figures in figure 4.2 are rotated to match the orientation of the images in figure 4.1. Each of the images is tested by attempting to match the phone from the test figure. The actual match should be around (170, 176). An exact result cannot be estimated as the images are not matched perfectly - there isn't an exact integer of pixel difference between the images. This is the sub pixel problem([Haller and Nedevschi \(2012\)](#)).

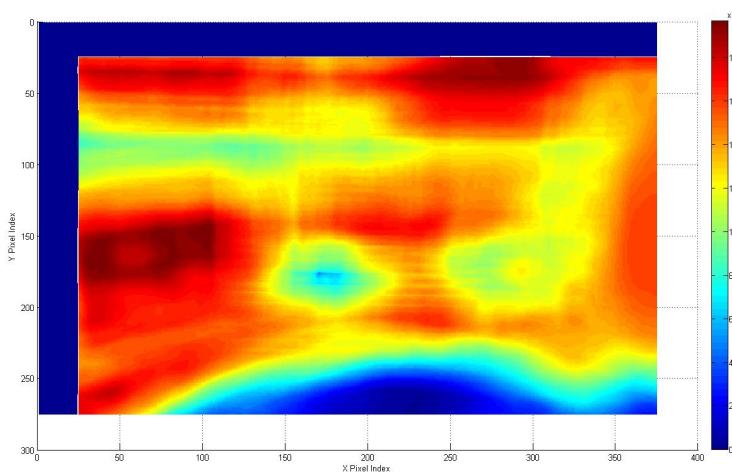

SAD results in figure 4.2(b) show large areas of matching. The actual match is at (170, 175) and a minimum does occur at this position as expected, of a value of 5.66×10^4 . However, along the bottom of the image, where a dark area occurs in the lower part of figures 4.1 below the desk, the SAD algorithm detects a greater comparison with the lowest value in this area being 3370 at (227, 275). This creates a false detection here.

SSD shows matches in the same two areas: where a match should occur and the dark area beneath the desk. The minimum values where the match should occur is 4.355×10^5 at location (170, 176). However, there is a large match correlation between the dark area under the desk where the actual lowest value of 2.768 occurs at (225, 274). This, again, is a false match and is a downfall of this algorithm.

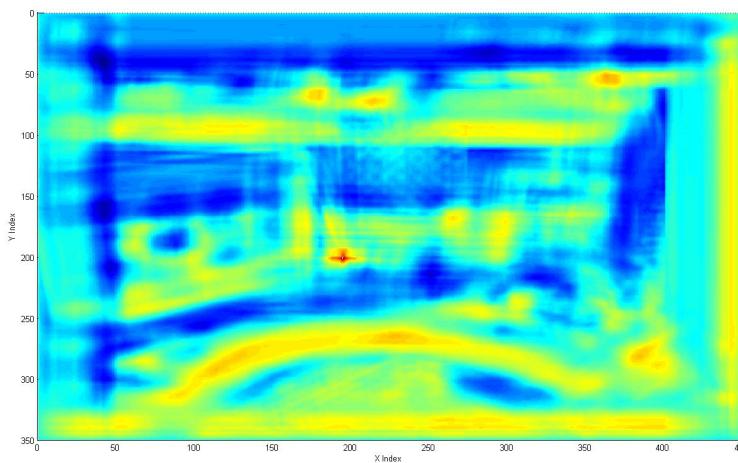

The NCC results are visible in figure 4.2(c). A match can be seen at coordinate (195, 201) with a peak value of 0.9654. The coordinate is different to the previous results because the cross correlation works over the boundary of the image creating more results. The dimensions of the image are 300×400 , but the NCC returns an data set of dimensions 350×450 when using a box size of 50×50 . To get the actual match, half of the box size must be subtracted from the returned coordinate.

(a) S.A.D. Results (Low match)

(b) S.S.D. Results (Low match)

(c) N.C.C. Results (High match)

Figure 4.2: Result Graphs of Comparison Algorithms

This means the match occurs at (170, 176). With this algorithm, there is no area of the image which is close to a false detection.

4.1.5 Conclusion

It can be seen that there is a direct correlation between the complexity of the matching algorithm to the reliability of the match returned. In brightly lit, colourful environments absent of dark colours, SAD and SSD should provide a reliable result, but this cannot be guaranteed to always be the case. Therefore further development of the matching algorithm will start with using the normalised cross correlation. A comprise between complexity and reliability needs to be reached, where reliability is the more desirable of the two. Cross correlation is also a large area of research, so optimised algorithms do exist.

4.2 Range Finding

4.2.1 Derivations

By using two images separated by a horizontal difference, the range of an object can be found given some characteristics of the camera. The following is a derivation of the equations used to calculate distance.

The problem is broken down into three parts:

1. Object is between the cameras (Figure 4.3)
2. Object is in left or right hand sides of both images (Figure 4.5)
3. Object is directly in front of a camera (Figure 4.6)

4.2.1.1 Object is between the Cameras

Derivation from [Mrovlje and Vrančić \(2008\)](#).

$$B = B_1 + B_2 = D \tan(\varphi_1) + D \tan(\varphi_2) \quad (4.4)$$

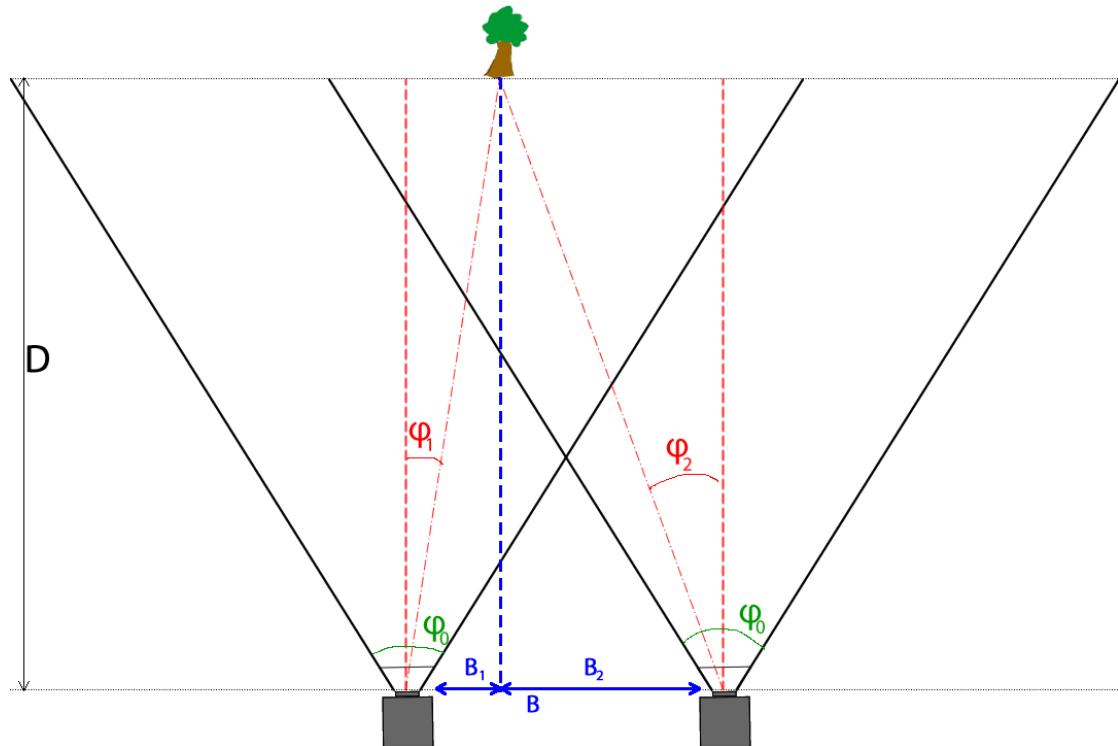

Figure 4.3: Problem 1 - Object is between the Cameras

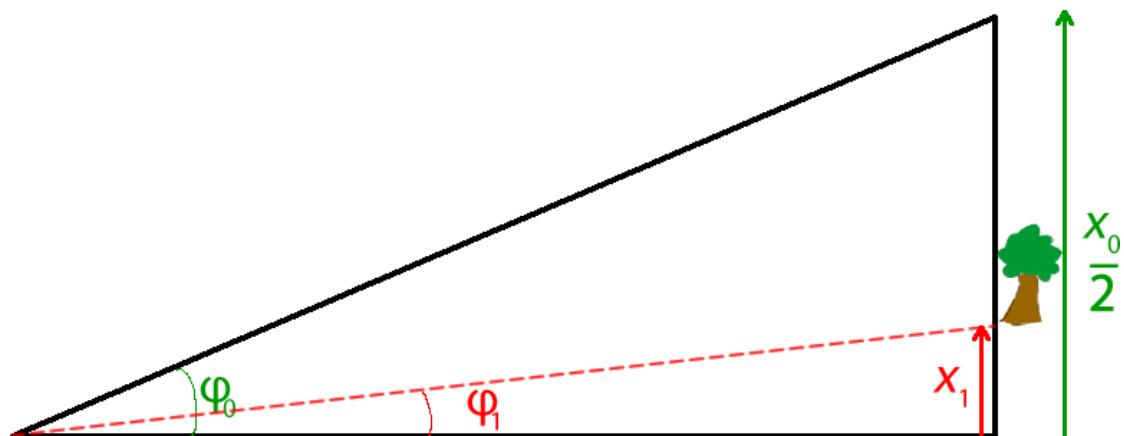

Figure 4.4: Problem 1 : Left Camera Simplified

$$D = \frac{B}{\tan(\varphi_1) + \tan(\varphi_2)} \quad (4.5)$$

$$D \tan\left(\frac{\varphi_0}{2}\right) = x_0/2 \quad (4.6)$$

$$D \tan(\varphi_1) = x_1 \quad (4.7)$$

Dividing (4.7) by (4.6)

$$\frac{\tan(\varphi_1)}{\tan(\frac{\varphi_0}{2})} = \frac{2x_1}{x_0} \quad (4.8)$$

$$\tan(\varphi_1) = \frac{2x_1 \tan(\frac{\varphi_0}{2})}{x_0} \quad (4.9)$$

This can also be shown for the right camera:

$$\tan(\varphi_2) = \frac{-2x_2 \tan(\frac{\varphi_0}{2})}{x_0} \quad (4.10)$$

Substitution equations (4.9) and (4.10) into (4.5) gives

$$D = \frac{Bx_0}{2 \tan(\frac{\varphi_0}{2})(x_1 - x_2)} \quad (4.11)$$

4.2.1.2 Object is to the same side in each camera

Derivation is based on the derivation from Tjandranegara (2005). Using figure 4.5:

$$D \cdot \tan(\varphi_1) = x_1 \quad (4.12)$$

$$D \cdot \tan(\frac{\varphi_1}{2}) = \frac{x_0}{2} \quad (4.13)$$

$$\frac{\tan(\varphi_1)}{\tan(\frac{\varphi_0}{2})} = \frac{2x_1}{x_0} \quad (4.14)$$

$$\varphi_1 = \arctan\left(\frac{2x_1}{x_0} \tan\left(\frac{\varphi_0}{2}\right)\right) \quad (4.15)$$

and similarly

$$\varphi_2 = \arctan\left(\frac{2x_2}{x_0} \tan\left(\frac{\varphi_0}{2}\right)\right) \quad (4.16)$$

$$\theta = \varphi_2 - \varphi_1 \quad (4.17)$$

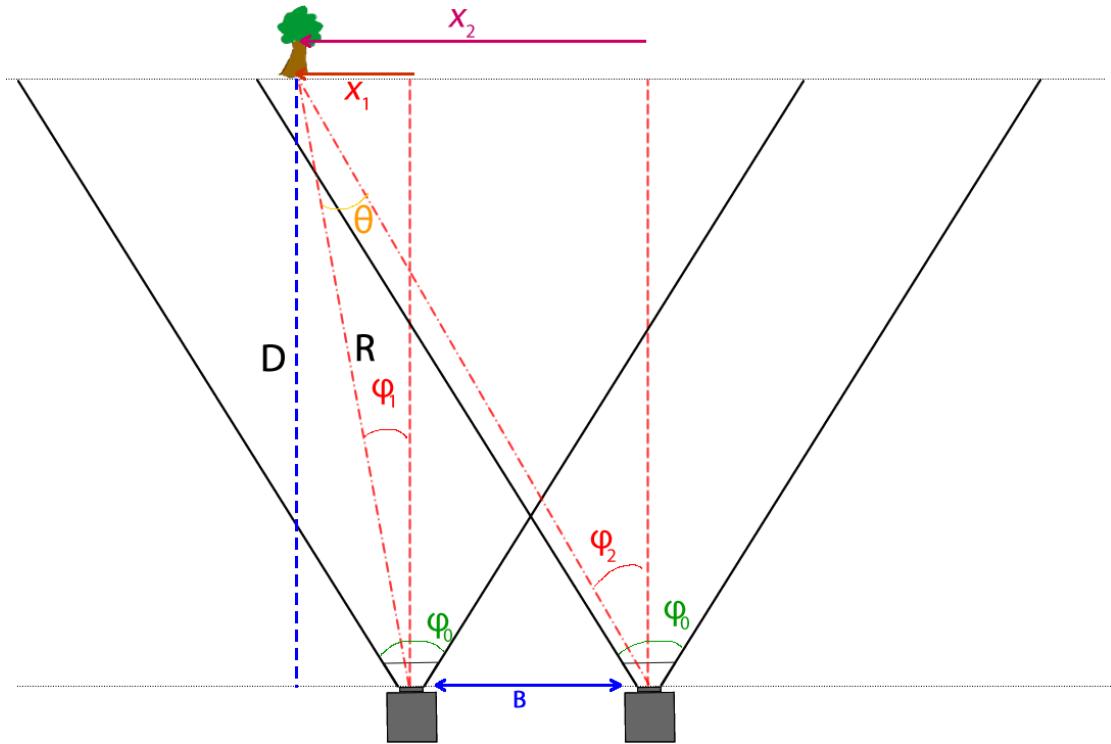

Figure 4.5: Problem 2 - Object is to the same side in both cameras

Using the sine equality rule:

$$\frac{R}{\sin(\frac{\pi}{2} - \varphi_2)} = \frac{B}{\sin(\theta)} \quad (4.18)$$

$$R = B \cdot \frac{\sin(\frac{\pi}{2} - \varphi_2)}{\sin(\theta)} = B \frac{\cos(\varphi_2)}{\sin(\theta)} \quad (4.19)$$

$$D = \cos(\varphi_1) \cdot R \quad (4.20)$$

Substituting (4.17) into (4.19), and then into (4.20):

$$D = B \cdot \frac{\cos(\varphi_2) \cdot \cos(\varphi_1)}{\sin(\varphi_2 - \varphi_1)} \quad (4.21)$$

Where φ_1 is defined in equation (4.15) and φ_2 is defined in equation (4.16).

4.2.1.3 Object is in front of a camera

The distance, D , in this problem is given by:

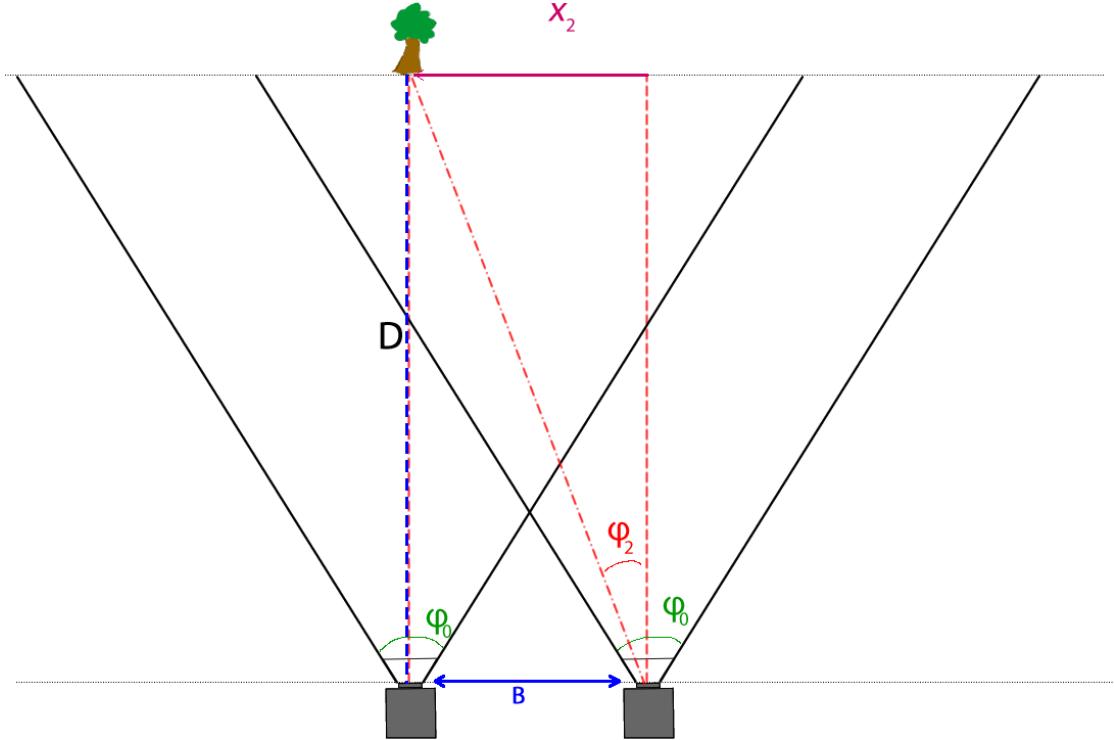

Figure 4.6: Problem 3 - Object is directly in front of a camera

$$D = B \tan\left(\frac{\pi}{2} - \varphi_2\right) \quad (4.22)$$

Where φ_2 can be found from equation 4.16.

4.2.1.4 Summary

There are three situations that can occur. These are listed below with their equations.

Object is between the two cameras:

$$D = \frac{Bx_0}{2 \tan\left(\frac{\varphi_0}{2}\right)(x_1 - x_2)} \quad (4.23)$$

Object is to the same side in both images:

$$D = B \cdot \frac{\cos(\varphi_2) \cdot \cos(\varphi_1)}{\sin(\varphi_2 - \varphi_1)} \quad (4.24)$$

Object is directly in front of a camera:

$$D = B \tan\left(\frac{\pi}{2} - \varphi_2\right) \quad (4.25)$$

Where φ_1 is defined in equation (4.15) and φ_2 is defined in equation (4.16).

When the images have been matched, these equations can be used to calculate the range to an object.

Chapter 5

Conclusions and Further Work

So far, the project has addressed three aspects of the whole design: image acquisition, object matching a range finding. All these aspects have been developed separately on different platforms; on an ATMega644P or in MATLAB.

A full image can be read from a camera and stored on an SD card in a FAT32 filesystem. This gives the ability of removable memory that can be viewed on a computer to see any internal logs. Images are stored in QVGA format (320 by 240 pixels) as a bitmap image.

Multiple comparison algorithms have been investigated and compared using the same test image. It was clear that, although at a sacrifice of computations, the normalised cross correlation is the best with regard to overall reliability.

Range finding equations were then derived, which use the characteristics of the camera and the separation distance between them.

The next steps will be bringing the comparison and range equations together so as to be able to choose an object in a scene and find the range to said object. Object detection algorithms need to be looked into so that an object in view can be detected and correctly located.

Robot movement also needs development. An accurate method to move a distance will be implemented with a proportional or PID controller.

A printed circuit board will also be designed with an AVR32 as the microcontroller and all extra hardware on the board will be included. This will then mean all modules (image acquisition, comparison, range finding etc.) can be ported to the

AVR32 and the robot can be made mobile. Further parts can then be developed such as the occupancy map and search algorithms.

All modules will be tested before being implemented. The final hardware design and development is to be completed by 15th March 2013 and the project report hand-in date is 1st May 2013.

Bitmap File Format

.1 Bitmap File Format

Table 1: Format of a Bitmap file with values used, to write an image from the camera to an SD Card

Section	Field	Description	Size (Bytes)	Value (hex)
Bitmap Header	Signature	Declares the file is a Bitamp Image	2	424D
	File Size	Size of the whole file including headers	4	36580200 (153654) ¹
	Reserved		4	00000000
	Offset to Pixel Array	The address of the start of the pixel data from the beginning of the file	4	36000000
DIB (Device Independant Bitmap) Header	Size	Size of the DIB Header (dictates the version)	4	7C000000
	Width	Width of the image (320 pixels)	4	40010000
	Height	Height of the image (240 pixels)	4	F0000000
	Planes	Number of colour planes	2	0100

Continued on next page

¹This is different to the 225kB said in Table 3.1 due to omitting many optional fields

Table 1 – continued from previous page

Section	Field	Description	Size (Bytes)	Value (hex)
	Bit Count	Number of bits per pixel	2	1000
	Compression	Compression Being Used, RGB Bit Fields	4	03 00 00 00
	Image Size	Size of the image	4	00 86 25 00
	X Resolution	Horizontal resolution in pixels per metre	4	13 0B 00 00
	Y Resolution	Vertical resolution in pixels per metre	4	13 0B 00 00
	Colours in Table	Number of colours in the colour table (not used)	4	00 00 00 00
	Important Colours	Number of Important Colours (0 means all colours are important)	4	00 00 00 00
	Red Mask	Bit mask of Red field	4	00 F8 00 00
	Green Mask	Bit mask of Green field	4	E0 07 00 00
	Blue Mask	Bit mask of Blue field	4	1F 00 00 00
	Alpha Mask	Bit mask of Alpha field	4	00 00 00 00
	Colour Space Type	Colour Space of the DIB	4	01 00 00 00
	Colour Space Endpoints	Sets endpoints for colours within the bitmap (not used)	36	Whole Field = 0
	Gamma Red	Gamma Value of Red Field (not used)	4	00 00 00 00
	Gamma Green	Gamma Value of Green Field (not used)	4	00 00 00 00
	Gamma Blue	Gamma Value of Blue Field (not used)	4	00 00 00 00

Continued on next page

Table 1 – continued from previous page

Section	Field	Description	Size (Bytes)	Value (hex)
	Intent	Enum dictating the intent of the image (Picture)	4	03 00 00 00
	ICC Profile Data	Offset from the file start to the ICC Colour Profile (Not Used)	4	00 00 00 00
	ICC Profile Size	Size of the ICC Colour Profile (not used)	4	00 00 00 00
	Reserved		4	00 00 00 00
Image Data Format	Each field contains all the pixel data	Padding is used to make the table width a multiple of 4 (Not always needed)		
Pix[0, h-1]	Pix[1, h-1]	...	Pix[w-1, h-1]	Padding
:	:	:	:	:
Pix[0, 1]	Pix[1, 1]	...	Pix[w-1, 1]	Padding
Pix[0, 0]	Pix[1, 0]	...	Pix[w-1, 0]	Padding

113 Call this function to resend the last message. The driver will reuse the data
114     previously put in the transceiver buffers.
115     The function will hold execution (loop) until the TWI_ISR has completed with
116     the previous operation,
117     then initialize the next operation and return.
118 ****
119 void TWI_Start_Transceiver( void )
120 {
121     while ( TWI_Transceiver_Busy() ); // Wait until TWI is ready for
122         next transmission.
123     TWI_statusReg.all = 0;
124     TWI_state = TWI_NO_STATE ;
125     TWCR = (1<<TWEN)| // TWI Interface enabled.
126         (1<<TWIE)|(1<<TWINT)| // Enable TWI Interrupt and
127         clear the flag.
128         (0<<TWEA)|(1<<TWSTA)|(0<<TWSTO)| // Initiate a START condition.
129         (0<<TWWC); // 
130 }
131
132 ****

```

```

120 Call this function to read out the requested data from the TWI transceiver
121 buffer. I.e. first call
122 TWI_Start_Transceiver to send a request for data to the slave. Then Run this
123 function to collect the
124 data when they have arrived. Include a pointer to where to place the data and
125 the number of bytes
126 requested (including the address field) in the function call. The function
127 will hold execution (loop)
128 until the TWI_ISR has completed with the previous operation, before reading
129 out the data and returning.
130 If there was an error in the previous transmission the function will return
131 the TWI error code.

9 * Updated by : Author: mlarsson
10 *
11 * Support mail : avr@atmel.com
12 *
13 * Supported devices : All devices with a TWI module can be used.
14 *                      The example is written for the ATmega16
15 *
16 * AppNote : AVR311 - TWI Slave Implementation
17 *
18 * Description : This is sample driver to AVRs TWI module.
19 *                 It is interrupt driven. All functionality is controlled
20 *                 through
21 *                 passing information to and from functions. See main.c for
22 *                 samples
23 *                 of how to use the driver.

53 Call this function to set up the TWI slave to its initial standby state.
54 Remember to enable interrupts from the main application after initializing the
55 TWI.

```

```

55     Pass both the slave address and the requirements for triggering on a general
56     call in the
57     same byte. Use e.g. this notation when calling this function:
58     TWI_Slave_Initialise( (TWI_slaveAddress<<TWI_ADR_BITS) | (TRUE<<TWI_GEN_BIT) )
59     ;
60     The TWI module is configured to NACK on any requests. Use a
61     TWI_Start_Transceiver function to
62     start the TWI.
63     ****
64     void TWI_Slave_Initialise( unsigned char TWI_ownAddress )
65     {
66         TWAR = TWI_ownAddress;                                // Set own TWI slave
67         address. Accept TWI General Calls.
68         TWCR = (1<<TWEN) |                                // Enable TWI-interface
69         and release TWI pins.
70         (0<<TWIE)|(0<<TWINT)|                            // Disable TWI Interrupt.
71         (0<<TWEA)|(0<<TWSTA)|(0<<TWSTO)|                // Do not ACK on any
72         requests, yet.
73         (0<<TWWC);                                       //
74         TWI_busy = 0;
75     }
76
77     ****
78     Call this function to test if the TWI_ISR is busy transmitting.
79     ****
80     unsigned char TWI_Transceiver_Busy( void )
81     {
82         return TWI_busy;
83     }
84
85     ****
86     Call this function to fetch the state information of the previous operation.
87     The function will hold execution (loop)
88     until the TWI_ISR has completed with the previous operation. If there was an
89     error, then the function
90     will return the TWI State code.
91     ****
92     unsigned char TWI_Get_State_Info( void )
93     {
94         while ( TWI_Transceiver_Busy() ) {}                  // Wait until TWI has
95         completed the transmission.
96         return ( TWI_state );                               // Return error state.
97     }
98
99     ****
100    Call this function to send a prepared message, or start the Transceiver for
101        reception. Include
102        a pointer to the data to be sent if a SLA+W is received. The data will be
103        copied to the TWI buffer.
104        Also include how many bytes that should be sent. Note that unlike the similar
105        Master function, the
106        Address byte is not included in the message buffers.
107        The function will hold execution (loop) until the TWI_ISR has completed with
108        the previous operation,
109        then initialize the next operation and return.
110        ****
111        void TWI_Start_Transceiver_With_Data( unsigned char *msg, unsigned char
112            msgSize )

```

```

99  {
100    unsigned char temp;
101
102    while ( TWI_Transceiver_Busy() ) {} // Wait until TWI is ready
103      for next transmission.
104
105    TWI_msgSize = msgSize; // Number of data to transmit.
106    for ( temp = 0; temp < msgSize; temp++ ) // Copy data that may be
107      transmitted if the TWI Master requests data.
108    {
109      TWI_buf[ temp ] = msg[ temp ];
110
111      TWI_statusReg.all = 0;
112      TWI_state = TWI_NO_STATE ;
113      TWCR = (1<<TWEN)| // TWI Interface enabled.
114        (1<<TWIE)|(1<<TWINT)| // Enable TWI Interrupt and
115        clear the flag.
116        (1<<TWEA)|(0<<TWSTA)|(0<<TWSTO)| // Prepare to ACK next time
117        the Slave is addressed.
118        (0<<TWWC); // /
119      TWI_busy = 1;
120    }
121
122  ****
123  Call this function to start the Transceiver without specifying new transmission
124    data. Useful for restarting
125  a transmission, or just starting the transceiver for reception. The driver
126    will reuse the data previously put
127  in the transceiver buffers. The function will hold execution (loop) until the
128    TWI_ISR has completed with the
129  previous operation, then initialize the next operation and return.
130  ****
131  void TWI_Start_Transceiver( void )
132  {
133    while ( TWI_Transceiver_Busy() ) {} // Wait until TWI is ready
134      for next transmission.
135    TWI_statusReg.all = 0;
136    TWI_state = TWI_NO_STATE ;
137    TWCR = (1<<TWEN)| // TWI Interface enabled.
138      (1<<TWIE)|(1<<TWINT)| // Enable TWI Interrupt and
139      clear the flag.
140      (1<<TWEA)|(0<<TWSTA)|(0<<TWSTO)| // Prepare to ACK next time
141      the Slave is addressed.
142      (0<<TWWC); // /
143    TWI_busy = 0;
144  }
145  ****
146  Call this function to read out the received data from the TWI transceiver
147    buffer. I.e. first call
148  TWI_Start_Transceiver to get the TWI Transceiver to fetch data. Then Run this
149    function to collect the
150  data when they have arrived. Include a pointer to where to place the data and
151    the number of bytes
152  to fetch in the function call. The function will hold execution (loop) until
153    the TWI_ISR has completed
154  with the previous operation, before reading out the data and returning.
155  If there was an error in the previous transmission the function will return
156    the TWI State code.

```
